CORRESPONDENCE COVER SHEET
WASTE PERMITS DIVISION
TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

Date: 01/20/2022
Facility Name: Pirkey Power Plant
Permit or Registration No.: Pending

Nature of Correspondence:
☒ Initial/New
☐ Response/Revision*

*If Response/Revision, please provide previous TCEQ Tracking No.:
(Previous TCEQ Tracking No. can be found in the Subject line of the TCEQ's response letter to your original submittal.)

This cover sheet should accompany all correspondences submitted to the Waste Permits Division and should be affixed to the front of your submittal as a cover page. Please check the appropriate box for the type of correspondence being submitted. For questions regarding this form, please contact the Waste Permits Division at (512) 239-2335.

- TCEQ Application
- Section 2 Supplement – TCEQ ePay
- Section 13 Supplement – Property and Legal Description
- Section 17 Supplement – Legal Authority
- Maps and Drawings
- Attachment 1 – Location Restrictions and Geology Reports
- Attachment 2 – Design Criteria for CCR Landfills and Surface Impoundments
- Attachment 3 – Operating Criteria for CCR Landfills and Surface Impoundments

TCEQ Application

Texas Commission on Environmental Quality

Registration Application for Coal Combustion Residuals (CCR) Waste Management

I. General Information

1. Reason for Submittal

Type of Registration Application

☒ New ☐ Major Amendment ☐ Minor Amendment

☐ Notice of Deficiency (NOD) Response ☐ Transfer ☐ Name Change

☐ Other

2. Application Fees (See Section 2 Supplement)

☒ $150 Application Fee

Payment Method

☐ Check ☒ Online through ePay portal <www3.tceq.texas.gov/epay/>

If paid online, enter ePay Trace Number: 582EA000467916

3. Facility Information

Facility information must match regulated entity information on the Core Data Form.

Applicant: ☐ Owner ☐ Operator ☒ Owner/Operator

Facility TCEQ Solid Waste Registration No: 33240

Facility EPA ID: TXD000726380

Regulated Entity Reference No. (if issued): RN 100214287

Facility Name: Pirkey Power Plant

Facility (Area Code) Telephone Number: 903-927-5883

Facility physical street address (city, state, zip code, county): 2400 FM 3251, Hallsville, TX 75650-7634

Facility mailing address (city, state, zip code, county): 2400 FM 3251, Hallsville, TX 75650-7634

Latitude (Degrees, Minutes Seconds): 32.4625

Longitude (Degrees, Minutes Seconds): -94.482777

4. Publicly Accessible Website

Provide the URL address of a publicly accessible website where the owner or operator of a CCR unit will post information.
http://www.aep.com/environment/ccr/Pirkey

5. Facility Landowner(s) Information

Facility landowner(s) name: American Electric Power/ Southwestern Electric Power Company

Facility landowner mailing address: 2400 FM 3251

City: Hallsville State: Texas Zip Code: 75650-7634

(Area Code) Telephone Number: 903-927-5883

Email Address (optional):

6. CCR Waste Management Unit(s)

☒ Landfill Unit(s) ☒ Surface Impoundment(s)

For each existing landfill, new landfill and lateral expansion, existing surface impoundment, and new surface impoundment and lateral expansion(s) provide information on type of waste, the registered unit(s) in which they are managed, and sampling and analytical methods.

Submit the following tables:

Table I.6. – CCR Waste Management Units;

Table I.6.A. – Waste Management Information;

Table I.6.B. – Waste Managed in Registered Units; and

Table I.6.C. – Sampling and Analytical Methods.

7. Description of Proposed Activities or Changes to Existing Facility

Provide a brief description of the proposed activities if application is for a new facility, or the proposed changes to an existing facility or registration conditions, if the application is for an amendment.
Single unit lignite-fired steam electric power generation plant utilizing 4 CCR management units

8. Primary Contact Information

Contact Name: Leslie Fuerschbach Title: Engineer

Contact mailing address: 502 North Allen Ave.
City: Shreveport County: Caddo State: LA Zip Code: 71102
(Area Code) Telephone Number: 318-673-2744

Email Address (optional): lefuerschbach@aep.com

9. Notice Publishing

Party responsible for publishing notice:
☒ Applicant ☐ Consultant ☐ Agent in Service

Contact Name: Leslie Fuerschbach Title: Engineer

Contact mailing address: 502 N. Allen Ave.
City: Shreveport County: Caddo State: LA Zip Code: 71102
(Area Code) Telephone Number: 318-673-2744

10. Alternative Language Notice

Is an alternative language notice required for this application? For determination, refer to Alternative Language Checklist on the Public Notice Verification Form (TCEQ-20244-Waste-NORI).

☐ Yes ☒ No

11. Public Place Location of Application

Name of the Public Place: Marshall Public Library
Physical Address: 300 South Alamo
City: Marshall County: Harrison State: TX Zip Code: 75670
(Area code) Telephone Number: (903) 935-4465

12. Ownership Status of the Facility

☒ Corporation ☐ Limited Partnership
☐ Sole Proprietorship ☐ General Partnership ☐ Other (specify):

Does the Site Owner (Permittee/Registrant) own all the CCR units and all the facility property?

☒ Yes ☐ No

13. Property / Legal Description Information (See Section 13 Supplement)

Provide a legal description and supporting documents of the property where the management of CCR waste will occur; including a survey plat and a boundary metes and bounds description (30 TAC §352.231(g)).

Submit the following documents:

a. Property Legal Description
b. Property Metes and Bounds Description
c. Metes and Bounds Drawings
d. On-Site Easements Drawings

14. Operator Information

Identify the entity who will conduct facility operations, if the owner and operator are not the same.

Operator Name: Same as Facility operator

Operator mailing address:

City: State: Zip Code:

(Area Code) Telephone Number:

Email Address (optional):

15. Confidential Documents

Does the application contain confidential documents?

☐ Yes ☒ No

If "Yes", cross-reference the confidential documents throughout the application and submit as a separate attachment in a binder clearly marked "CONFIDENTIAL."

16. Permits and Construction Approvals

Permit or Approval	Received	Pending	Not Applicable
Hazardous Waste Management Program under the Texas Solid Waste Disposal Act	☐	☐	☒
Underground Injection Control Program under the Texas Injection Well Act	☐	☐	☒
National Pollutant Discharge Elimination System Program under the Clean Water Act and Waste Discharge Program under Texas Water Code, Chapter 26	☒	☐	☐
Prevention of Significant Deterioration Program under the Federal Clean Air Act (FCAA). Nonattainment Program under the FCAA	☒	☐	☐
National Emission Standards for Hazardous Air Pollutants Preconstruction Approval under the FCAA	☒	☐	☐
Other (describe)	☐	☐	☐
Other (describe)	☐	☐	☐
Other (describe)	☐	☐	☐

17. Legal Authority (See Section 17 Supplement)

The owner and operator of the facility shall submit verification of their legal status with the application. This shall be a one-page certificate of incorporation issued by the secretary of state. The owner or operator shall list all persons having over a 20% ownership in the facility.

18. TCEQ Core Data Form CN 600126767 RN 100214287

The TCEQ requires that a Core Data Form (TCEQ-10400) be submitted on all incoming applications, unless a Regulated Entity and Customer Reference Number has been issued by the TCEQ and no core data information has changed. For more information regarding the Core Data Form, call (512) 239-5175 or visit the TCEQ Website.

19. Other Governmental Entities Information

Coastal Management Program

Is the facility within the Coastal Management Program boundary?

☐ Yes ☒ No

Local Government Jurisdiction (If Applicable)
Within City Limits of:
Within Extraterritorial Jurisdiction of:

Is the facility located in an area in which the governing body of the municipality or county has prohibited the storage, processing or disposal of municipal or industrial solid waste?

☐ Yes ☒ No If "Yes", provide a copy of the ordinance or order as an attachment.

20. Attachments (See Maps and Drawings)

Does the application include the following?

General Maps	☒ Yes	☐ No
General Topographic Map	☒ Yes	☐ No
Facility Layout Map	☒ Yes	☐ No
Surrounding Features Map	☒ Yes	☐ No
Process Flow Diagram	☒ Yes	☐ No
Land Ownership Map	☒ Yes	☐ No
Land Ownership List	☒ Yes	☐ No
Pre-printed Mailing Labels	☒ Yes	☐ No

Maps and drawings shall be legible and easily readable by eye without magnification. Scales and paper size shall be chosen based on the type of map submitted, the land area covered, and the amount of detail to be shown. See instructions for details regarding maps and drawings to be submitted in application.

21. Verification of Compliance

Does the owner and operator verify that the design, construction, and operation of CCR landfill(s) and surface impoundment(s) meets the requirements of 30 TAC §352.231(f) (30 TAC §352.2; 40 CFR §257.52, and 40 CFR §§257.3-1 – 257.3-3).

☒ Yes ☐ No

II. Location Restrictions and Geology

See Instructions and Technical Guidance

22. Location Restrictions (See Attachment 1 – 1.1 to 1.4)

Submit certifications and technical reports demonstrating compliance of CCR unit(s) with applicable location restrictions (30 TAC 352, Subchapter E) and comply with 30 TAC §352.231(d) and 30 TAC §352.4 for submission of engineering and geoscientific information.

A. **Placement above the uppermost aquifer** (30 TAC §352.601) (40 CFR §257.60). For those CCR units whose base is less than five feet above the upper limit of the uppermost aquifer, please submit a copy of the demonstration showing evidence of compliance with 40 CFR §257.60(a) – (c).

B. **Wetlands** (30 TAC §352.611) (40 CFR §257.61). For CCR units located in wetlands, please submit a copy of the demonstration showing evidence of compliance with 40 CFR §257.61(a) – (c).

C. **Fault areas** (30 TAC §352.621) (40 CFR §257.62). For CCR units located within 200 feet of the outermost damage zone of a fault, please submit a copy of the demonstration showing evidence of compliance with 40 CFR §257.62(a) – (c).

D. **Seismic impact zones** (30 TAC §352.631) (40 CFR §257.63). For CCR units located in a seismic impact zone, please submit a copy of the demonstration showing evidence of compliance with 40 CFR §257.63(a) – (c).

E. **Unstable areas** (30 TAC §352.641) (40 CFR §257.64). For CCR units located in unstable areas, please submit a copy of the demonstration showing evidence of compliance with 40 CFR §257.64(a) – (d).

23. Geology Summary Report (See Attachment 1 – 1.1 to 1.4, Section 2.4 of each Location Restriction Report)

Submit a summary of the geologic conditions at the facility, including the relation of the geologic condition to each CCR unit. The summary must include enough information and data and include sources and references for the information. Include all groundwater monitoring data required by 40 CFR Part 257, Subpart D, (30 TAC §352.241, §352.601, §352.621, §352.631, and §352.641) and submitted in accordance of 30 TAC §352.4.

Note: Previously prepared documents may be submitted but must be supplemented or updated as necessary to provide the requested information (30 TAC §352.241(b)).

III. Fugitive Dust Control Plan

24. Fugitive Dust Control Plan (See Attachment 3 – 3.1 and 3.2)

A. **Submit a copy of the CCR Fugitive Dust Control Plan** (30 TAC §352.801) (40 CFR §257.80(b)), or the most recently amended plan. The initial plan or subsequent amended plan must be certified by a qualified Texas licensed professional engineer (Texas P.E.) that the plan meets the requirements of 30 TAC Chapter 352.

B. Submit the most recent Annual CCR Fugitive Dust Control Report (30 TAC §352.801) (40 CFR §257.80(c)) and include the report information.

IV. Landfill Criteria

See Instructions and Technical Guidance – No. 30 Coal Combustion Residuals Landfill

25. Landfill(s) for CCR Waste (See Attachments 1, 2 and 3, more detail below)

Provide the following information below if there is a landfill; if there is more than one landfill, separate information is required for each landfill.

A. Landfill Characteristics (Attachment 1 – 1.3 and 1.4, Section 2.2 of Location Restriction Reports; Attachment 2 – 2.1)

Describe the design, installation, construction, and operation of the landfill and submit a completed Table IV.A. – Landfill Characteristics.

B. Liner Design (Attachment 2 – 2.1)

1. For existing landfills, provide attachments describing how the facility will comply with 30 TAC 352, Subchapter F (Design Criteria).
2. For new landfills or lateral expansions of existing landfills, submit pages describing how the facility will comply with 30 TAC §352.261 and 30 TAC §352.701.
3. Complete Table IV.B. - Landfill Liner System and specify the type of liner used for the landfill.
4. Provide attachments describing the design, installation, and operation of the liner and leak detection system. The description must demonstrate that the liner and leak detection system will prevent discharge to the land, groundwater, and surface water. Submit a quality assurance project plan (QAPP) to ensure that each analysis is performed appropriately.

C. Leachate Collection and Removal (Attachment 2 – 2.1)

Submit design information and description of leachate collection and removal system in accordance with 30 TAC §352.701.

Complete Table IV.C. - Landfill Leachate Collection System

D. Design of Liner and Leachate Collection and Removal System. (Attachment 2 – 2.1)

For a new landfill or lateral expansion of a CCR landfill, provide a qualified Texas P.E. certification and technical report that the design of the liner and the leachate collection and removal system meets the requirements of 30 TAC §352.711.

E. Run-on and Run-off Controls (Attachment 3 – 3.3 and 3.4)

At time of application, attach pages describing how the facility will comply with the run-on and run-off system plan for an existing, new, or lateral expansion of a CCR landfill information. Provide a qualified Texas P.E. certification and technical report that the run-on and run-off control system plans meet the requirements of 30 TAC §352.811.

F. Inspection for Landfills (Attachment 3 – 3.7 and 3.8)

At time of application, attach pages describing how the facility will comply 30 TAC §352.841 and complete Table IV.D. – Inspection Schedule for Landfills. For existing CCR landfills, provide the most recent inspection report. All CCR landfills and any lateral expansions of a CCR landfill must be inspected for any structural weakness, malfunction, deterioration conditions which are disrupting or have the potential to disrupt the operation or safety of the CCR unit, or any other conditions which may cause harm to human health and environment at a frequency specified in 40 CFR §257.84(a) and (b).

V. Surface Impoundment Criteria

See Instructions and Technical Guidance – No. 31 Coal Combustion Residuals Surface Impoundment

26. Surface Impoundment(s) for CCR Waste (See Attachments 2 and 3, more detail below)

Provide the following information below if there is a surface impoundment; if there is more than one surface impoundment, separate information is required for each surface impoundment.

A. General Surface Impoundment(s) Characteristics (Attachment 2 – 2.5)

Provide information about the characteristics of the surface impoundment(s): incised, surface area (acres), storage volume (acres-feet), and depth (feet).

For all surface impoundment(s), include the following information:

1. Complete Table V.A. - Surface Impoundments Characteristics. List the surface impoundment(s) to be registered as a CCR unit(s), the wastes managed in each unit, and the rated capacity or size of each unit.
2. Describe the surface impoundment(s) and provide a plan view drawing with cross-sections, if available.
3. Specify the minimum freeboard to be maintained and the basis of the design to prevent overtopping resulting from normal or abnormal operation; overfilling; wind and wave action; rainfall; run-on; malfunctions of level controllers, alarms, and other equipment; and human error. Show that adequate freeboard will be available to prevent overtopping from a 100-year, 24-hour storm.
4. Waste Flow
   Describe the means that will be used to immediately shut off the flow of waste to the impoundment in the event of liner failure or to prevent overtopping.
5. Dike Construction ☒ Yes ☐ No

   If Yes, submit the dike certification (located at the end of the application).

   The structural integrity of the dike system must be certified by a qualified Texas P.E. before the registration is issued. If the impoundment is not being used, the dike system must be certified before it can be put into use. The certification must be sealed by a qualified Texas P.E., along with the engineering firm's name and registration number (30 TAC §352.4).

A report shall accompany the dike certification which summarizes the activities, calculations, and laboratory and field analyses performed in support of the dike certification. Describe the design basis used in construction of the dikes. A QAPP should be included in the report to ensure that each analysis is performed appropriately and include:

(1) Slope Stability Analysis

(2) Hydrostatic and Hydrodynamic Analysis

(3) Storm Loading

(4) Rapid Drawdown

Earthen dikes should have a protective cover to minimize wind and water erosion and to preserve the structural integrity of the dike. Describe the protective cover used and describe its installation and maintenance procedures.

B. Liner Design (Attachment 2 – 2.2 and 2.3)

For surface impoundment(s), provide information about how the facility will comply with 30 TAC §352.711 for existing CCR surface impoundments. For new and lateral expansion of CCR surface impoundments provide information on how the facility will comply with 30 TAC §352.261, and 30 TAC §352.721, see Instructions and Technical Guidance No. 31 Coal Combustion Residuals Surface Impoundment. The qualified Texas P.E. must certify that the design of the liner complies with the requirements of 30 TAC Chapter 352 and 40 CFR Part 257, Subpart D, where required.

Is the CCR surface impoundment unlined? ☒ Yes ☐ No

If "Yes", the CCR unit is subject to the closure requirements under 30 TAC Chapter 352 and 40 CFR §257.101(a) to retrofit or close. A notification must be prepared stating that an assessment of corrective measures has been initiated.

1. Complete Table V.B. - Surface Impoundment Liner System for each surface impoundment to be registered.
2. Describe the design, installation and operation of liner and leak detection components. The description must demonstrate that the liner and leak detection system will prevent discharge to the land and surface water. Submit a QAPP report to ensure that each analysis is performed appropriately.
3. For new or laterally expansions of existing surface impoundments, provide a subsurface soil investigation report that must include:
    a. A description of all borings drilled, at the unit location, to test soils and characterize groundwater;
    b. A unit map drawn to scale showing the surveyed locations and elevations of the borings, including location of permanent identification markers ((30 TAC §352.731) and (40 CFR §257.73(a)(1));
    c. Cross-sections prepared from the borings depicting the generalized strata at the unit;
    d. Boring logs, including a description of materials encountered, and any discontinuities such as fractures, fissures, slickensides, lenses or seams;
    e. A description of the geotechnical data and the geotechnical properties of the subsurface soil materials, including the suitability of the soils and strata for the intended uses; and

f. A demonstration that all geotechnical tests were performed in accordance with industry practices and recognized procedures.

C. Hazard Potential Classification (Attachment 2 – 2.4 and 2.8)

Provide the current hazard potential classification assessment and associated documentation, as required by 30 TAC §352.731 or §352.741 and 40 CFR §257.73(a)(2) or §257.74(a)(2). The qualified Texas P.E. must certify that the initial hazard potential classification and any subsequent periodic classification was conducted in accordance with the requirements of 30 TAC Chapter 352, where required.

Hazard Potential Classification: **Both the EBAP and WBAP are Low Hazard Potential**

D. Emergency Action Plan for High or Significantly High Hazard Potential (not applicable)

Provide the current Emergency Action Plan that has been certified by a qualified Texas P.E. and includes the following requirements from 30 TAC 352, Subchapter F and 40 CFR §257.73(a)(3)(i)(A) - (E) or 40 CFR §257.74 (a)(3)(i)(A) - (E). The qualified Texas P.E. must certify that the written Emergency Action Plan and any subsequent amendment of the plan complies with the requirements of 30 TAC 352, Subchapter F, where required.

Complete Table V.J. - Inspection of Surface Impoundments

E. Inflow Design Flood Control System Plan (Attachment 3 – 3.5)

Describe how the surface impoundment(s) system will manage stormwater run-on away from the surface impoundment(s) (30 TAC §352.821 and 40 CFR §257.82(a) and (c)). Stormwater run-on must be diverted away from a surface impoundment, based on the hazard potential. Where dikes are used to divert run-on, they must be protected from erosion. Include all analyses used to calculate run-on volumes. Provide the inflow design flood control system plan. Provide qualified Texas P.E. certification that the initial and periodic inflow design flood control system plans meet the requirements of 30 TAC §352.821, where required.

F. History of Construction for Existing CCR Surface Impoundment(s), or the Design and Construction Plans for New and Lateral Expansions (Attachment 2 – 2.5)

Provide information on the history of construction for each existing CCR surface impoundment (30 TAC §352.731 and 40 CFR §257.73(c)) or the design and construction plans for new and lateral expansions of each CCR surface impoundment (30 TAC §352.741) and (40 CFR §257.74(c)).

G. Structural Stability Assessment (Attachment 2 – 2.6)

Provide the most recent structural stability assessment of the surface impoundments. Include the combined capacity of all surface impoundment spillways with calculations; the peak discharge the unit must meet for all combined spillways; probable maximum flood-high hazard, 1,000-yr-significant high hazard, 100-yr-low hazard; identify if there were any structural stability deficiencies in last assessment; identify how these deficiencies were managed and corrected; and qualified Texas P.E. certification. The structural stability assessment must include all information required in 30 TAC §352.731 for existing surface impoundments or 30 TAC §352.741 for new or laterally expanding surface impoundments.

H. **Safety Factor Assessment (Attachment 2 – 2.7 and 2.9)**

The current safety factor assessment must be submitted with the application. It must include documentation that demonstrates whether the calculated factors of safety for each CCR surface impoundment achieve the minimum safety factors specified in 30 TAC 352, Subchapter F and 40 CFR §257.73(e)(1)(i) - (iv) and 40 CFR §257.74(e)(1)(i) - (iv) for the critical cross-section of the embankment. The critical cross-section is the cross-section anticipated to be the most susceptible to structural failure based on appropriate engineering considerations, including loading conditions. The safety factor assessments must be supported by appropriate engineering calculations and certified by a qualified Texas P.E.

VI. Groundwater Monitoring and Corrective Action (30 TAC 352, Subchapter H)

See Instructions and Technical Guidance – No. 32 Coal Combustion Residuals Groundwater Monitoring and Corrective Action

27. Groundwater Monitoring System (See Attachment 4 – 4.1 to 4.4)

A. Complete Table VI.A. - Unit Groundwater Detection Monitoring System.

B. Provide a map showing location of wells, groundwater elevations, and groundwater flow direction.

C. Provide attachments describing how the facility will comply with the requirements in 30 TAC §352.911 and provide a certification by a qualified Texas P.E or qualified Texas P.G. that the groundwater monitoring system design and construction meet the requirements of 30 TAC Chapter 352.

D. Provide a figure showing the geologic units and fill materials overlying the uppermost aquifer, materials comprising the uppermost aquifer, and materials comprising the confining unit defining the lower boundary of the uppermost aquifer, including, but not limited to, thicknesses, stratigraphy, lithology, hydraulic conductivities, porosities and effective porosities.

E. For a multiunit groundwater monitoring system, demonstrate that the groundwater monitoring system will be equally as capable of detecting monitored constituents at the waste boundary of the CCR unit as the individual groundwater monitoring system for each CCR unit by providing at minimum the following information:

1. Number, spacing, and orientation of each CCR unit;
2. Hydrogeologic setting; and
3. Site history.

F. Has there been any sampling concentrations of one or more constituents listed in Appendix IV detected at statistically significant levels above the groundwater protection standard (GWPS)? ☒ Yes ☐ No

G. Provide information on how monitoring wells have been constructed and cased in a manner that maintains the integrity of the monitoring well borehole and to prevent contamination of samples and the groundwater.

28. Groundwater Monitoring Sampling and Analysis Program (See Attachment 4 – 4.5 and 4.6)

Provide a sampling and analysis plan that includes procedures and techniques; sampling and analytical methods that are appropriate for groundwater sampling; and that address the requirements of 30 TAC §352.931 and 40 CFR §257.93. Provide a P.E or P.G. certification that describes the statistical method selected to evaluate the groundwater monitoring data and certifies that the selected statistical method is appropriate for evaluating the groundwater monitoring data for the CCR management area. Refer to TG-32 for information and guidance.

29. CCR Unit(s) in a Detection Monitoring Program (See Attachment 4 – 4.7 to 4.9)

Does the facility have CCR unit(s) in a Detection Monitoring Program?

☒ Yes ☐ No

If "Yes", Submit the following information:

A. Submit Table VI.C. – Facility CCR Units Under Detection Monitoring.

B. Provide a Background Evaluation Report.

C. Provide a report with the results of semiannual monitoring events.

1. Has a statistically significant increase (SSI) been detected for one or more of the constituents listed in Appendix III at any monitoring well?

   ☐ Yes ☒ No

2. Has a notification to the executive director been sent within 14 days?

   ☐ Yes ☒ No

3. Date assessment monitoring program will start: NA
4. Do you plan to provide an alternative source demonstration (ASD)?

   ☐ Yes ☒ No

30. CCR Unit(s) in an Assessment Monitoring Program (See Attachment 4 – 4.10 to 4.18)

Does the facility have CCR unit(s) in an Assessment Monitoring Program?

☒ Yes ☐ No

If "Yes", Submit information related for units.

A. Complete Table VI.D. – CCR Units Under Assessment Monitoring.

B. Provide, for each well in assessment monitoring status, the recorded concentrations lab sheets and results in a tabulated form.

C. Have the concentrations of all constituents listed in Appendices III and IV been at or below background values, using the statistical procedures in 30 TAC §352.931 and 40 CFR §257.93(g), for two consecutive sampling events for the CCR unit(s)? ☐ Yes ☒ No

If answer to above is yes, detection monitoring may resume. The owner or operator must prepare a notification stating that detection monitoring is resuming for the CCR unit and obtain written approval from the executive director.

D. Are there any concentrations of any constituent in Appendices III and IV above background values? ☒ Yes ☐ No

1. Has a notification to the executive director been sent within 14 days?

   ☒ Yes ☐ No

E. Date assessment of corrective measures will be initiated (must be within **90 days** of finding a statistically significant level above the GWPS) for the CCR unit(s):
NA

F. Will you provide an ASD (see TG-32 for an acceptable submittal)? ☒ Yes ☐ No

G. Date assessment of corrective measures will be initiated if ASD is not accepted?
90 days after receiving TCEQ's denial of the submitted ASD

H. Complete Table VI.D-2. - Groundwater Detection Monitoring Parameters

Note: Refer to TG-32 regarding establishing a GWPS for each constituent in Appendix IV detected in the groundwater and attach as table.

I. Have you completed the assessment of corrective measures? ☐ Yes ☒ No
If "Yes", date assessment of corrective measures was completed:
If "No", date assessment of corrective measures will be completed:
Expected date of submittal of amendment (see note below):
Provide completed assessment of corrected measures materials.

Note: Within **30 days** of completing the assessment of corrective measures, and before remedy implementation, the owner or operator shall submit an application for amendment to the registration. In some circumstances, the assessment of corrective measures and selected remedy may be approved as part of the initial application for the CCR unit registration.

J. Have you selected a remedy? ☐ Yes ☒ No

Provide public meeting documentation under 30 TAC §352.961 and a report under 30 TAC §352.971 and 40 CFR §257.97.

VII. Closure and Post-Closure Care

See Instructions and Technical Guidance

Submit a full closure plan and post-closure plan and all information describing how the owner or operator will comply with 30 TAC 352, Subchapter J and 40 CFR §§257.100 - 257.104. The owner of property on which an existing disposal facility is located, following the closure of a unit, must also submit documentation that a notation has been placed in the deed to the facility that will in perpetuity notify any potential purchasers of the property that the land has been used to manage CCR wastes and its use is restricted (30 TAC §352.1221 and 40 CFR §257.102(i)). For CCR units, closed after October 19, 2015, that were closed before submission of the application, the applicant should submit documentation to show that notices required under 30 TAC 352, Subchapter K and 40 CFR §257.105 or §257.106 have been filed.

31. Closure Plan (See Attachment 5 – 5.1 to 5.4)

This section applies to the owners and operators of all CCR units required to be registered. The applicant must close the facility in a manner that minimizes need for further maintenance and controls, or eliminates, to the extent necessary to protect human health and the environment, the post-closure release of CCR waste, chemical constituents of concern, leachate, contaminated rainfall, or waste decomposition products to the groundwater, surface waters, or to the atmosphere.

The type of unit to be closed can determine the level of detail sufficient for a closure plan. CCR units which have been certified closed after October 19, 2015, must provide documentation to demonstrate compliance with state and federal regulations.

For each unit to be registered, complete Table VII.A.1. - Unit Closure and list the CCR Unit components to be decontaminated, possible methods of decontamination, and possible methods of disposal of wastes and waste residues generated during unit closure. All ancillary components must be decontaminated, and the generated waste disposed of appropriately.

Information about CCR units closed or to be closed under alternative closure requirements must be provided in Table VII.A.2. - CCR Units Under Alternative Closure Notification.

Guidance on design of a closure cap and final cover for non-hazardous industrial solid wastes landfills is provided in EPA publication 530-SW-85-014, TCEQ Technical Guidance No. 3 and TCEQ publication, RG-534, “Guidance for Liner Construction and Testing for a Municipal Solid Waste Landfill”.

32. Post-Closure Care Plan (See Attachment 6 – 6.1 to 6.3)

Provide a post-closure care plan that complies with the requirements of 30 TAC §352.1241. Post-closure care of each CCR unit must continue for at least 30 years after the date of completing closure of the unit and must consist of monitoring and reporting of the groundwater monitoring systems, in addition to the maintenance and monitoring of CCR unit. Continuation of certain security requirements may be necessary after the date of closure. Post-closure use of property on or in which waste remains after closure must never be allowed to disrupt the integrity of the containment system. In addition, submit the following information:

- The name, address, and phone number of the person or office to contact about the CCR unit during the post-closure period; and
- A discussion of the future use of the land associated with each unit.

Landfills and surface impoundments which have been certified closed after October 19, 2015, must be included in post-closure care plans, unless they have been determined to have been closed by waste removal equivalent to the closure standards in 30 TAC §352.1221 and 40 CFR §257.102 or 30 TAC §352.1231 and 40 CFR §257.103. If such a demonstration has been made pursuant to 40 CFR §257.102 or §257.103, but an equivalency determination has not been made, please submit a copy of the demonstration documentation. If an equivalency determination has been made, applicant should submit a copy of this determination.

VIII. Financial Assurance

33. Post-Closure Care Cost Estimate (See Attachment 7)

Financial assurance for post-closure care (30 TAC §352.1101) applies to owners or operators of all CCR units, except CCR units from which the owner or operator intends to remove wastes and perform clean closure. Provide a written cost estimate in current dollars of the total cost of the 30-year (or longer, if applicable under 30 TAC §352.1101(d)) post-closure care period to perform post-closure care requirements as prescribed in 30 TAC §352.1241. The cost estimate must be based on the costs of hiring a third party to conduct post-closure care maintenance.

Complete Table VIII.A.1 – Post-Closure Cost Summary for Existing Registered Units

Complete Table VIII.A.2. - Post-Closure Cost Summary for Proposed Registered Units

34. Financial Assurance Mechanism

The financial assurance for post-closure care is required in accordance with 30 TAC §352.1101. The applicant shall demonstrate the financial assurance within 90 days after approval of the registration with a financial mechanism acceptable to TCEQ in compliance with 30 TAC §352.1101(c) and 30 TAC §37, Subchapters A through D, except as indicated in 30 TAC §352.1111, in an amount no less than the amount specified in the approved Post-Closure Care Cost Summary. Provide a description of the proposed financial assurance mechanism.

Complete Table VIII.B. - Post-Closure Period, for the authorized post-closure period, to meet the requirements of 30 TAC §352.1241(a) through (c).

Table I.6. – CCR Waste Management Units

CCR Unit No.[1]	Unit Name	N.O.R. No.[1]	Unit Description[3]	Capacity	Unit Status[2]
	East Bottom Ash Pond (EBAP)	005	Ash transport Wastewater Pond	300,000 cubic yards	Active
	West Bottom Ash Pond (WBAP)	005	Ash transport Wastewater Pond	300,000 cubic yards	Active
	Landfill (LF)	003	Ash Landfill	16.5 million cubic yards	Active
	FGD Stackout Area (FGDSA)	023	Radial Stack Out Area and Conveyor Belts	30,000 cubic yards	Active

1 Registered Unit No. and N.O.R. No. cannot be reassigned to new units or used more than once.
2 Unit Status options: Active, Closed, Inactive (built but not managing waste), Proposed (not yet built), Never Built, Transferred, Post-Closure.
3 If a unit has been transferred, the applicant should indicate which facility/permit it has been transferred to in the Unit Description column.

Table I.6.A. – Waste Management Information
East Bottom Ash Pond

Waste No.[1]	Waste Type(s)	Source	Volume (tons/year)
0016	Solid	Generated on-site from a product process or service activity	278,781
0019	Liquid	Generated on-site from a product process or service activity	Water is recirculated as part of plant process
0024	Liquid	Generated on-site from a product process or service activity	Water is recirculated as part of plant process

Landfill and FGD Stackout Area

Facility Unit(s) and Basic Elements	Possible Error, Malfunction, or Deterioration	Frequency of Inspection
Landfill	Discolored Discharge	7 Days
Landfill	Unexplained Increase or Decrease in Discharge	7 Days
Landfill	Uncontrolled Seepage/Leachate Outbreak	7 Days
Landfill	Unintended Ponded Water at Toe of Slope	7 Days
Landfill	Wet Surface on Slope (Indication of Potential Seepage)	7 Days
Embankment	Ruts, Depressions, Settlement, or Misalignment	7 Days
Embankment	Cracks, Bulges, or Slope Failure	7 Days
Control Features	Damage or Blockage to Drainage Feature	7 Days
Control Features	Malfunctioning Gate, Valve, Stop Log, Pump, or Related Structures	7 Days
Control Features	Unintended Ponded Water Along Ditch or Channel	7 Days
Surface	Minor or Major Erosion	7 Days
Surface	Displaced Riprap or Stone	7 Days
Surface	Visible Fugitive Dust	7 Days
Surface	Animal Activity	7 Days
Surface	Excessive Vegetation	7 Days
Surface	Bare or Missing Vegetation	7 Days
Surface	Damage to Stairs, Walkways, Ramps, Platforms, or Liners	7 Days

Table V.A. – Surface Impoundment Characteristics

Registered Unit No.	Surface Impoundment Name	N.O.R. No.	Waste Nos.[1]	Rated Capacity	Dimensions[2]	Distance from lowest liner to groundwater	Action Leakage Rate (if required)	Unit will manage CCR Waste and non-CCR Waste (state all that apply)
	EBAP	005	0016 0019 0024 0212 0230	300,00 cubic yards	30 acres; L = 1180 ft W = 1100 ft D = 7.5 ft	NA	NA	Both CCR and non-CCR waste
	WBAP	005	0016 0019 0024 0212 0230	300,00 cubic yards	30 acres; L = 1380 ft W = 950 ft D = 7.5 ft	NA	NA	Both CCR and non-CCR waste

1 From Table I.6.A., first column
2 Dimensions should be provided as average length, width and depth, also include the surface acreage for the unit.

Table V.B. – Surface Impoundment Liner System

Registered Unit No.*	Surface Impoundment Name	Geomembrane Liner Material	Geomembrane Liner Permeability (cm/sec)	Geomembrane Liner Thickness	Soil Liner Material	Soil Liner Permeability (cm/sec)	Soil Liner Thickness
	EBAP	NA	NA	NA			
	WBAP	NA	NA	NA			

* This number should match the Registration Unit No. given on Table V.A.

Table V.J. – Inspection Schedule of Surface Impoundments

Facility Unit(s) and Basic Elements	Possible Error, Malfunction, or Deterioration	Frequency of Inspection
EBAP/WBAP	Discolored Discharge	7 Days
EBAP/WBAP	Unexplained Increase or Decrease in Discharge	7 Days
EBAP/WBAP	Uncontrolled Seepage/Leachate Outbreak	7 Days
EBAP/WBAP	Unintended Ponded Water at Toe of Slope	7 Days
EBAP/WBAP	Wet Surface on Slope (Indication of Potential Seepage)	7 Days
Embankment	Ruts, Depressions, Settlement, or Misalignment	7 Days
Embankment	Cracks, Bulges, or Slope Failure	7 Days
Control Features	Damage or Blockage to Drainage Feature	7 Days
Control Features	Malfunctioning Gate, Valve, Stop Log, Pump, or Related Structures	7 Days
Control Features	Unintended Ponded Water Along Ditch or Channel	7 Days
Surface	Minor or Major Erosion	7 Days
Surface	Displaced Riprap or Stone	7 Days
Surface	Visible Fugitive Dust	7 Days
Surface	Animal Activity	7 Days
Surface	Excessive Vegetation	7 Days
Surface	Bare or Missing Vegetation	7 Days
Surface	Damage to Stairs, Walkways, Ramps, Platforms, or Liners	7 Days

Lithium	Semi annual	EPA 200.8-1994, Rev. 5.4	0.0002 ppm	0.0170 ppm

Parameter	Sampling Frequency	Analytical Method	Practical Quantification Limit (units)	Concentration Limit[1]
Mercury	Semi annual	EPA 245.7-2005, Rev. 2.0	0.005 ppb	0.0020 ppm
Molybdenum	Semi annual	EPA 200.8-1994, Rev. 5.4	2 ppb	0.005 ppm
Selenium	Semi annual	EPA 200.8-1994, Rev. 5.4	0.2 ppb	0.050 ppm
Thallium	Semi annual	EPA 200.8-1994, Rev. 5.4	0.5 ppb	0.002 ppm
Radium 226+228	Semi annual	SW-846 9320-2014,Rev. 1.0/SW-846 9315-1986,Rev. 0	0.5 pCi/L	5pCi/L

1 The concentration limit is the basis for determining whether a release has occurred from the CCR unit/area.

Table VII.A.1. – Unit Closure

For each unit to be registered, list the unit components to be decontaminated, the possible methods of decontamination, and the possible methods of disposal of wastes and waste residues generated during unit closure.

Equipment or CCR Unit	Possible Methods of Decontamination[1]	Possible Methods of Disposal[1]
Landfill	Closure in place	Landfill
FGD Stackout Area	Closure by removal	Landfill

1 Applicants may list more than one appropriate method.

Registration No.: 33240
Registrant: American Electric Power/Southwestern Power Company

Table VII.A.2. – CCR Units Under Alternative Closure Notification

Registered Unit No.	N.O.R. Unit No.	Unit Description[1,2]	Date of Receipt of Last Waste[3]	Date of Closure Notification[3]
	005	EBAP		
	005	WBAP		

1 Indicates a unit for which a 30 TAC Chapter 352/40 CFR Part 257, Subpart D alternative closure determination has been requested pursuant to 40 CFR §257.103.

2 Indicates a unit for which a 30 TAC Chapter 352/40 CFR Part 257, Subpart D alternative closure determination has been made pursuant to 40 CFR §257.103.

3 Enter month, day, and year.

Table VIII.A.1. – Post-Closure Cost Summary for Existing Registered Units

Unit	Cost
Landfill (see attached spreadsheet for details)	$102,500 (annually)
Total Existing Unit Post-Closure Cost Estimate	$3,075,000(in 2021 Dollar)[1]

Table VIII.A.2. - Post-Closure Cost Summary for Proposed Registered Units

Unit	Cost

1 As units are added or deleted from these tables through future registration amendments, the remaining itemized unit costs should be updated for inflation when re-calculating the revised total cost in current dollars.

Table VIII.B. – Post-Closure Period

Unit Name	Date Certified Closed	Authorized Post-Closure Period (Yrs.)	Earliest Date Post-Closure Ends (See Note 1)
Landfill		30 years	

Note 1 – Post-Closure Care shall continue beyond the specified date until the Executive Director has approved the applicant's request to reduce or terminate the post-closure period, consistent with 30 TAC §352.1241 – Post-Closure Care Requirements.

13. Property / Legal Description Information

Provide a legal description and supporting documents of the property where the management of CCR waste will occur; including a survey plat and a boundary metes and bounds description (30 TAC §352.231(g) – property owner information shall be provided in the application in accordance with 330.59(d) of this title, except 330.59(d)(2)(B) of this title.)

SECTION 330.59. Contents of Part I of the Application

(d) Property owner information. Property owner information shall include the following:

(1) the legal description of the facility;

(A) the legal description of the property and the county, book, and page number or other generally accepted identifying reference of the current ownership record;

(B) for property that is platted, the county, book, and page number or other generally accepted identifying reference of the final plat record that includes the acreage encompassed in the application and a copy of the final plat, in addition to a written legal description;

(C) a boundary metes and bounds description of the facility signed and sealed by a registered professional land surveyor (D) drawings of the boundary metes and bounds description; and

(2) a property owner affidavit signed by the owner that includes the following:

(A) acknowledgment that the State of Texas may hold the property owner of record either jointly or severally responsible for the operation, maintenance, and closure and post-closure care of the facility; and

(C) acknowledgment that the facility owner or operator and the State of Texas shall have access to the property during the active life and post-closure care period, if required, after closure for the purpose of inspection and maintenance:

"I Gary O. Spitznogle as Vice President of Environmental Services
(print Signatory Name) (Signatory Capacity)

as authorized signatory for **Pirkey Power Plant**, acknowledge that the State of Texas may hold me either jointly or severally responsible for the operation, maintenance and closure and post-closure care of the facility. For the facility where waste will remain after closure, I acknowledge that I have a responsibility to file with the county deed records an affidavit to the public advertising that the land will be used for a solid waste facility prior to the time that the facility actually begins operating and to file a final recording upon completion of disposal operations and closure of the landfill unit(s) in accordance with **Title 30 Texas Administrative Code 352.1221**, **Criteria for Conducting the Closure or Retrofit of Coal Combustion Residual Units**. I further acknowledge that I or the operator at the State of Texas shall have access to the property during the active life and post-closure care period."

CONVEYANCE AND BILL OF SALE

FILED FOR RECORD
84 JUN 14 A 9:50
GLENN L[illegible]
CO CLERK, HARRISON CO
BY ________ DEP

THE STATE OF TEXAS

COUNTY OF HARRISON

KNOW ALL MEN BY THESE PRESENTS:

THAT, Southwestern Electric Power Company, a Delaware corporation authorized to do business in the State of Texas, (herein sometimes called Grantor and sometimes called SWEPCO, for a valuable and adequate consideration paid by Northeast Texas Electric Cooperative, Inc., a cooperative corporation organized and existing under the laws of the State of Texas, hereinafter sometimes called Grantee and sometimes called NTEC (the address of which is P.O. Box 70, Gilmer, Texas, 75644), has GRANTED, SOLD and CONVEYED, and does by these presents GRANT, SELL and CONVEY unto the said Northeast Texas Electric Cooperative, Inc., its successors and assigns, subject to the conditions, exceptions and reservations set out herein, an undivided 11.72% of Grantor's right, title and interest in the following property and rights, to-wit:

A. Grantor's right, title and interest in and to the lands described in Exhibit "A" attached hereto and made a part hereof, reference to which is here made for a better description thereof, which said Exhibit "A" describes 2,933.979 acres of land, more or less, in the Winny Mann Survey, A-439, Wm. Watson Survey, A-748, Zion Roberts Survey, A-595, L. B. Blankenship Survey, A-71, and J. B. Hill Survey, A-298, all in Harrison County, Texas, and 92.459 acres of land in the L. B. Blankenship Survey, A-71, and the J. M. Dorr Survey, A-4, Harrison County, Texas, for a total of 3026.438 acres, more or less.

B. Grantor's right, title and interest in and to any and all easements, permits, licenses, servitudes, and Agreements used or useful or held for future use in connection with said Exhibit "A" land, including but not limited to the water rights under and pursuant to that certain Agreement dated December 5, 1977, by and between Northeast Texas Municipal Water District and SWEPCO, and permits related thereto, except, however, this conveyance does not cover or include any interest in SWEPCO's transmission line and substation easements and related facilities located on or used in connection with said Exhibit "A" land.

C. Grantor's right, title and interest in and to any and all improvements, buildings, structures and appurtenances located on or used in connection with said Exhibit "A" lands including, but not limited to the facilities described in Exhibit "B" attached hereto and made a part hereof.

The interests and rights hereinabove described are herein referred to as the "Conveyed Properties."

TO HAVE AND TO HOLD the Conveyed Properties, together with all and singular all rights, appurtenances and hereditaments thereto in anywise belonging unto Grantee, its successors and assigns, subject, however, to the following conditions, reservations and exceptions, to-wit:

1. This conveyance does not cover or include the SWEPCO interest in the water and air pollution control facilities and solid waste disposal facilities covered by and described in the Installment Sales Agreement dated October 15, 1981 between The Sabine River Authority of Texas and SWEPCO, but this conveyance does cover all of the 11.72% interest therein which was retained by SWEPCO and excepted from said October 15, 1981 Agreement.

2. This Conveyance and Bill of Sale is subject to all of the terms, conditions, and provisions contained in that certain Ownership, Construction and Operating Agreement between Southwestern Electric Power Company and Northeast Texas Electric Cooperative, Inc. dated the 8th day of April, 1982, and amended January 13, 1983, and amended March 12, 1984, covering and relating to the HENRY W. PIRKEY UNIT NO. 1, a copy of which said Agreement can be examined for relevant purposes in the office of SWEPCO or in the office of NTEC.

3. It is understood and agreed that within the lands described in said Exhibit "A" there are certain tracts of land and interests in certain tracts of land which have not yet been acquired by SWEPCO. This conveyance covers an 11.72% of the interest which is owned by SWEPCO and which might hereafter be acquired by SWEPCO within the confines of the lands described in said Exhibit "A".

4. This conveyance is without any warranties, expressed or implied. All warranties from manufacturers, suppliers and contractors shall extend to NTEC to the extent of its ownership interest.

5. This conveyance is subject to any valid, existing easement, right-of-way, or oil, gas and mineral lease, or oil, gas or mineral conveyance or reservation of record in the Office of the County Clerk of Harrison County, Texas, and is further subject to the provisions of any Deed, Award of Special Commissioners, or Judgment in eminent domain proceedings in which SWEPCO acquired title to said land.

With reference to said Conveyed Properties, it is understood and agreed that under the terms of said OWNERSHIP, CONSTRUCTION AND OPERATING AGREEMENT referred to, as amended, from February 1, 1983 until April 1, 1983, NTEC paid 100% of the monthly costs, charges, and expenses connected with the acquisition, construction and maintenance of said Conveyed Properties, thereby acquiring an equitable right to 100% of the Conveyed Properties acquired from February 1, 1983 to April 1, 1983, and as a material part of the consideration for this Conveyance and Bill of Sale, NTEC has and does hereby ASSIGN, QUITCLAIM and CONVEY unto SWEPCO, its successors and assigns all of NTEC's right, title and interest in and to said Conveyed Properties over and above the undivided 11.72% owned by and vested in NTEC through this Conveyance and Bill of Sale, thereby vesting title to said Conveyed Properties in the following proportions:

SWEPCO:	88.28%
NTEC:	11.72%

EXECUTED the 14th day of June, 1984.

FIELD NOTES OF 92.459 ACRES OF LAND

Being 92.459 acres of land located in the L. B. Blankenship Survey A-71 and the J. M. Dorr Survey A-4, Harrison County, Texas, said 92.459 acres being more particularly described as follows:
BEGINNING at the NE Corner of the Zion Roberts Survey, A-595, said point being in the SBL of the L. B. Blankenship Survey; THENCE West 8,223.6 feet and North 1,647.2 feet to a 3/8" iron rod for the SW Corner and the place of BEGINNING of the herein described 92.459 acres of land for Railroad ROW;
THENCE along the West side of said ROW the following bearing and distances along a chord of a curve to the left N 34° 18' 05" W, 578.51 feet; S 87° 00' W, 517.85 feet; N 03° 37' 20" W, 498.58 feet; N 02° 38' 59" W, 32.67 feet; N 44° 30' 30" W, 355.09 feet; N 35° 12' 14" W, 123.56 feet; N 44° 30' 30" W, 493.01 feet; S 02° 24' 10" E, 487.09 feet; S 85° 05' 01" W, 100 feet; N 02° 24' 10" W, 631.85 feet; N 44° 30' 40" W, 658.88 feet; N 19° 54' 28" W, 565.22 feet; N 02° 00' W, 1220.15 feet; N 35° 12' 47" W, 1161.63 feet; N 04° 31' 07" W, 567.01 feet; N 04° 30' W, 370.02 feet; N 05° 16' 24" W, 348.06 feet; N 04° 57' 36" W, 1081.2 feet; N 13° 33' W, 1638.26 feet; N 00° 43' W, 645.76 feet; N 82° 42' E, 65 feet; N 21° 05' E, 209.53 feet; N 29° 53' E, 992.71 feet; N 20° 25' E, 496.67 feet; N 10° 26' E, 1188.81 feet; N 00° 39' W, 653.68 feet; N 25° 35' W, 488.62 feet; N 29° 17' W, 936.37 feet; N 29° 12' W, 357.91 feet; Along a chord of a curve to the left N 72° 35' W, 1155.75 feet; S 73° 35' W, 333.39 feet to a 3/8" iron rod for Corner in the South ROW of the Missouri Pacific Railroad;
THENCE N 59° 49' 30" E, 1039.1 feet along the South ROW of the existing Missouri Pacific Railroad to a 3/8" iron rod for Corner, said point being S 59° 11' W, 1821.41 feet from the NE Corner of 168 acre tract recorded in Vol. 566 Page 669 Deed Records of Harrison County, Texas;
THENCE along the East ROW line of the herein described ROW the following bearings and distances: S 25° 05' E, 92.37 feet; along a cord of a curve to the right S 52° 20' E, 908 feet; S 28° 00' E, 1376.61 feet; along a cord of a curve to the right S 07° 42' E, 1167.78 feet; S 12° 52' W, 1339.07 feet; S 26° 41' W, 1130.38 feet; S 27° 17' W, 280.02 feet; along a cord of a curve to the right S 02° 42' W, 864.53 feet; S 13° 04' E, 1253.52 feet; S 16° 37' E, 75.6 feet, S 13° 13' 37" E, 322.57 feet; S 08° 13' 05" W, 1003.65 feet; S 03° 56' 43" E, 306.96 feet; S 04° 30' 30" E, 502.48 feet; along the cord of a curve to the left S 14° 15' 57" E, 361.37 feet; S 51° 50' 26" E, 547.96 feet; S 20° 30' 36" E, 699.34 feet; S 02° 42' 06" E, 242.28 feet; S 02° 00' E, 1158.63 feet; along a cord of a curve to the left S 29° 13' 16" E, 562.25 feet; S 44° 30' 30" E, 200.0 feet; N 88° 16' 34" E, 720.6 feet; S 02° 32' 45" E, 183.63 feet; S 03° 56' 28" E, 465.73 feet; S 02° 39' 05" E, 125.9 feet; S 40° 24' 29" E, 268.19 feet; S 44° 30' 30" E, 636.12 feet; S 48° 22' E, 334.49 feet; S 18° 46' 16" E, 216.73 feet along a chord of a curve to the right; S 26° 12' E, 200.68 feet and S 87° 17' 37" W, 172.0 feet to the place of BEGINNING of the herein described Railroad ROW SAVE AND EXCEPT 1.36 acres for the crossing of Interstate Highway No. 20 and 0.33 acre for the crossing of Highway 968 and leaving a total of 92.459 net acres.

I, Lee W. Newman, Registered Public Surveyor, do hereby certify that the above plat and field notes correctly represent the results of a survey made on the ground.

WITNESS MY HAND AND SEAL this the 12th day of January, 1983.

Process Flow Description

Pirkey Power Plant

Water Balance Narrative (refer to Water Balance Diagram)

CCR Wastestreams:

The Bottom Ash Complex receives approximately 6.5 million gallons per day of sluiced water containing economizer and bottom ash. Pyrites, a non-CCR wastestream, are also managed with the CCR wastestreams.

AEP evaluated each CCR wastestream placed in the EBAP and WBAP at Pirkey Power Plant. For the reasons discussed below and in Table 1, the following CCR wastestreams must continue to be placed in the EBAP and WBAP due to lack of alternative capacity both on and off-site.

Table 1: Pirkey Power Plant CCR Wastestreams

CCR Wastestream	Average Flow (gpd)	Current Configuration	Alternative Capacity Currently Available? Yes/No	AEP Notes
Bottom Ash	6,500,000 (includes economizer ash and pyrites)	Bottom ash is currently alternately sluiced to the EBAP and WBAP. Ash from the pond not receiving sluice flows is cleaned with ash being transported to the onsite landfill.	No	There are currently no alternative CCR compliant ponds onsite and extensive modifications would be required to manage the bottom ash so that it could be disposed in the onsite landfill. These alternatives are not practicable for generating units that will retire in 2023.
Economizer Ash	Included with Bottom Ash flows	Sluiced to the existing EBAP and WBAP with bottom ash	No	There are currently no alternative CCR compliant ponds onsite and extensive modifications would be required to manage the economizer ash so that it could be disposed in the onsite landfill. These alternatives are not practicable for generating units that will retire in 2023.

CCR Wastestream	Average Flow (gpd)	Current Configuration	Alternative Capacity Currently Available? Yes/No	AEP Notes
Pyrites (non-CCR but handled with CCR wastestreams)	Included with Bottom Ash flows	Sluiced to the existing EBAP and WBAP using the existing bottom ash pumps and piping.	No	No alternate system is available for collection of pyrites which are comingled with bottom and economizer ash. Extensive modifications would be required to manage the pyrites so that it could be disposed in the onsite landfill. These alternatives are not practicable for generating units that will retire in 2023.

Pirkey Power Plant does not have an existing alternate impoundment on-site that meets the liner or aquifer separation requirements of EPA's CCR regulation, and considerable modifications to plant equipment, facilities, and processes will be necessary before Pirkey Power Plant can cease sluicing CCR and placing non-CCR wastestreams into the EBAP and WBAP. CCR sluicing flows are treated in the EBAP and WBAP to remove solids and then are recycled back to the plant for reuse. In order to meet the water quality requirements to support the plant operation and provide space for collection of solids, a new CCR compliant impoundment approximately 12 acres in size would be required. Since Pirkey Power Plant has elected to pursue the option to permanently cease combusting coal by a date certain, developing alternative disposal capacity is counterproductive to the work to retire the boilers and close the CCR surface impoundments. As EPA explained in the preamble of the 2015 rule, it is not possible for sites that sluice CCR material to an impoundment to eliminate the impoundment and dispose of the material offsite. See 80 Fed. Reg. 21,301, 21,423 (Apr. 17, 2015) ("[W]hile it is possible to transport dry ash off-site to [an] alternate disposal facility that is simply not feasible for wet-generated CCR. Nor can facilities immediately convert to dry handling systems."). A new CCR compliant impoundment would be required to treat the CCR flows as noted above.

If temporary frac tanks were used for treatment of the CCR sluice water and if 24 hours would provide sufficient residence time for the settling of the fine solids in the CCR wastestreams, approximately 650 frac tanks would be required to store and treat the bottom ash transport water. The number of tanks required was estimated by taking the total sluice flow (6.5 MGD) divided by the frac tank capacity (21,000 gallons) and doubling it to account for the 24 hours settling time requirement which resulted in 610 frac tanks. Because approximately 50 of these frac tanks would need to be rotated out of service each day for solids removal and disposal in the Pirkey landfill, an allowance, or emergency margin, of 50 frac tanks was added to this value, which resulted in a total of 660 tanks being required. These tanks would cover over 10 acres of the site. The tanks would require significant amounts of interconnecting piping which could create an unacceptable potential for significant leaks or spills.

For off-site disposal, 6.5 MGD on average would require approximately 866 trucks per day based on 7,500 gallons per truck to haul off and dispose of the water collected. This operation would need to take place 24 hours a day and 7 days a week and poses significant safety risks both on and off-site due to the truck traffic and is impossible to achieve.

The most likely facility type capable of managing industrial wastewaters are publicly-owned or private treatment works, underground injection wells, or publicly available waste management facilities capable of solidifying liquid wastes for disposal in a landfill. Given the volume and characteristics of the CCR wastestreams, increases in permitted capacity or other modifications to the permitted pretreatment programs of a public or private wastewater treatment facility would likely be required to manage this flow, if one were available. Off-site disposal is not an option for Pirkey Power Plant CCR material.

As a result, the conditions at Pirkey Power Plant satisfy the demonstration requirement in 40 CFR § 257.103(f)(2)(i) and in the interim period (prior to permanent cessation of the coal-fired boilers) Pirkey Power Plant must continue to use the EBAP and WBAP due to the absence of alternative disposal capacity both on and off-site of the facility.

Non-CCR Wastestreams:

Approximately 100,000 gallons per event of demineralizer regeneration waste.

AEP evaluated this non-CCR wastestream that is placed in the EBAP and WBAP at Pirkey Power Plant. For the reasons discussed below and in Table 2, this non-CCR wastestream must continue to be placed in the EBAP or WBAP due to lack of alternative capacity both on and off-site.

Table 2: Pirkey Power Plant non-CCR Wastestreams

Non-CCR Wastestream	Average Flow (gallons per event)	Current Configuration	AEP Notes
Demineralizer Regeneration Waste	100,000	Flows to the existing EBAP or WBAP	Regeneration of the existing anion and cation exchange resin beads occurs on a weekly basis as a batch treatment. The EBAP or WBAP provides treatment for this wastestream which allows it to be neutralized prior to returning to the plant. No alternative capacity exists for treatment.

Pirkey Power Plant does not have an existing alternate impoundment on-site that can be utilized for treatment of the non-CCR wastestream. As stated previously, since AEP has elected to pursue the option to permanently cease the use of the coal fired boilers by a certain date, developing alternative disposal capacity is “illogical,” to use EPA’s words, and also counterproductive to the work to retire the boilers and close the impoundments

There is currently no existing installed infrastructure at the plant to support reroute of these flows. Although this volume is significantly lower than the much larger volume of bottom ash transport water, rerouting this wastestream would require construction of additional treatment and storage capacity at the site, subject the facility to additional permitting obligations, and therefore is inconsistent with the work required to retire the unit and close the ponds.

Relative to the off-site disposal capacity for this non-CCR wastestream, the acidic nature of the wastestream makes it unacceptable at most off-site facilities without prior treatment. The most likely facility type capable of managing industrial wastewaters are publicly-owned or private treatment works, underground injection wells, or publicly available waste management facilities capable of solidifying liquid wastes for disposal in a landfill. Given the volume and characteristics of this non-CCR wastestream, increases in permitted capacity or other modifications to the permitted pretreatment programs of a public or private wastewater treatment facility would likely be required to manage this flow, if one were available.

There is neither on-site nor off-site capacity available to manage this non-CCR wastestream. Consequently, in order to continue to operate and generate electricity, Pirkey Power Plant must continue to use the Bottom Ash Complex to manage the non-CCR wastestream due to lack of alternative capacity both on and off-site.

Based on the evaluation of alternative disposal options, AEP selected the following options for compliance at Pirkey Power Plant:

- Cessation of the coal burning boilers
- Closure of the EBAP by CCR material removal.
- Closure of the WBAP by CCR material removal.

This strategy can be implemented in the least amount of time and accommodates the unique site features, quantity of wastestreams, and the lack of off-site disposal facilities.

Location Restrictions and Geology Reports

30 TAC §352.241- Geology

Location Restriction Reports containing a summary of the geologic conditions at the facility and were prepared and signed in accordance with 30 TAC §352.4. All groundwater monitoring data is located in the annual Groundwater Monitoring and Corrective Action Reports (see, Attachment 4b).

30 TAC §352.251 - Location Restriction Application Submission

These Location Restriction reports contain documentation demonstrating compliance with applicable location restrictions in Subchapter E of 30 TAC §352 and information required by Placement above the uppermost aquifer (30 TAC §352.601/40 CFR §257.60), Wetlands (30 TAC §352.611/40 CFR §257.61), Fault Areas (30 TAC §352.621/40 CFR §257.62), Seismic impact zones (30 TAC §352.631/40 CFR §257.63), and Unstable areas (30 TAC §352.641/40 CFR §257.64) were applicable.

Terms used in these reports comport with 30 TAC §352.3/40 CFR §257.53

Geology Summary Report – See Section 2.4 in the Location Restriction Report

Submit a summary of the geologic conditions at the facility, including the relation of the geologic condition to each CCR unit. The summary must include enough information and data and include sources and references for the information. Include all groundwater monitoring data required by 40 CFR Part 257, Subpart D, (30 TAC §352.241, §352.601, §352.621, §352.631, and §352.641) and submitted in accordance of 30 TAC §352.4.

TCEQ	Texas Commission on Environmental Quality

1. Objective

This report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to assess the location of the East Bottom Ash Pond relative to the location restrictions included in the Coal Combustion Residual (CCR) requirements, as specified in the Code of Federal Regulations (CFR) 40 CFR 257.60 to 257.64, at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The CCR requirements include an evaluation of the adequacy of the groundwater monitoring well network to characterize groundwater quality up and down gradient of the CCR unit and an evaluation of whether the CCR unit meets up to 5 location restrictions, which include: the base of the CCR unit is 5 feet (ft) above the uppermost aquifer, the CCR unit may not be located in a wetland, within 200 ft of the damage zone of a fault that has displacement during the Holocene, within a seismic impact zones, or in an unstable area.

Four regulated CCR units associated with the Plant were identified for review, which include the West Bottom Ash Pond (BAP), East BAP, Stack Out Area, and Landfill (**Figure 2**). This report summarizes the evaluation of the location restriction criteria at the East BAP (Site). The evaluation of the groundwater monitoring well network in the uppermost aquifer for the East BAP is not included in this report and will be completed under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the East BAP CCR unit, as well as publically-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on documents reviewed and will further describe the uppermost aquifer.

2. Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant East BAP.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The East BAP CCR unit is located at the north end of the Plant and approximately 2,000 feet north-northwest of Brandy Branch Reservoir (**Figures 1** and **2**).

2.2 Description of East Bottom Ash Pond CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the East BAP.

2.2.1 Embankment Configuration

The East BAP is partially incised into native soils with an embankment height of approximately 4 feet (AMEC, 2011). The East BAP embankments are constructed of compacted clay on a 3:1 slope (3 feet horizontal, 1 foot vertical) (Sargent & Lundy, 1983). The elevation of the top of the embankment around the perimeter of the East BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, May 2011). The interior bottom elevation of the East BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Johnson & Pace, June 2011).

2.2.2 Area/Volume

The East BAP is approximately 31.5 acres in size. The design maximum ash storage capacity of the East BAP is 188 acre feet (Sargent & Lundy, 1983). Johnson & Pace calculated the East BAP ash storage capacity in 2011 at 161 acre feet at an elevation of 355 feet amsl (maximum operating level) (Johnson & Pace, June 2011).

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant East BAP was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, flue gas desulfurization sludge) have been generated. The East BAP, which was placed into operation in 1985, receives bottom ash and economizer ash sluiced from the power plant boiler (**Figure 3**). Clear water overflow from the East BAP discharges into the Clearwater Pond located directly south of the East BAP. Bottom ash and economizer ash are periodically excavated from the East BAP and hauled by truck to either the on-site landfill for disposal, or for beneficial re-use.

The base of the East BAP was constructed in 1983 with a compacted clay liner (Sargent & Lundy, 1983). Following installation of the compacted clay liner, soil borings S-4 through S-7 were advanced below the base of the East BAP to total depths of six feet in September 1983 (Southwestern Laboratories, 1984). The lithologic data from soil borings S-4 through S-7 confirm at least six feet of clay is present below the base of the East BAP (Sargent & Lundy, 1984).

2.2.4 Surface Water Control

Surface water elevation in the East BAP is controlled by a weir box and a manually operated gate valve on a 36-inch-diameter discharge pipe at the southwest corner of the pond. Clear water overflow from the East BAP discharges through the 36-inch-diameter pipe into the 2.7- acre Clearwater Pond located directly south of the East BAP (Figure 3). Water in the Clearwater Pond is either pumped (re-circulated) back into the boiler ash hopper, or gravity discharged through a pipe at the southwest corner of the Clearwater Pond into an unnamed intermittent tributary of Hatley Creek via Outfall 006 in accordance with Texas Pollutant Discharge Elimination System (TPDES) Permit No. WQ0002496000.

2.3 Previous Investigations

The initial soils investigation and design of the East BAP was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, and design of the East BAP. As discussed above in Section 2.2.3, the design included installation of a clay liner below the East BAP.

In September-October 1983, Southwestern Laboratories conducted a soil investigation at the Plant, including advancement of four soil borings (S-4 through S-7) below the East BAP (Southwestern Laboratories, 1984).

In 1984, Sargent & Lundy conducted an evaluation of the East BAP. This report included evaluation of soil sample geotechnical data, and concluded a low-permeability clay liner was present below the East BAP (Sargent & Lundy, 1984).

In 2009, ETTL Engineers & Consultants (ETTL) conducted a geotechnical investigation of the East BAP earthen embankment. The investigation included installation of two soil borings through the embankment (E1, E2), completion of the soil borings as piezometers PE-1 and PE-2, respectively, and collection of soil samples for geotechnical analyses. The report concluded the embankment was stable and the existing embankment slopes were acceptable if conditions are maintained (ETTL, 2010). The conditions to be maintained included embankment protection from erosion (vegetative cover), removal of brush and trees two feet or more in height, and control of animal burrowing.

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, 2011).

In 2011, Johnson & Pace performed a hydraulic analysis of the East BAP for a 10-year, 24-hour rainfall event in accordance with the TCEQ TPDES permit design criteria. The report concluded the storage capacity of the East BAP is hydraulically adequate (Johnson & Pace, May 2011).

In 2015, Auckland Consulting further expended the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-30 through AD-35 (Auckland Consulting, 2016).

2.4 Hydrogeologic Setting

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Plant. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of approximately 100 feet (Broom, 1966).

These features are further illustrated on five lines of cross section that were prepared through the East BAP area, with three lines trending from west to east (A-A'; B-B'; C-C'), and the other two lines trending from north to south (D-D'; E-E'). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure 4** (A-A') through **Figure 8** (E-E').

2.4.1 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1° Fahrenheit (F) in January to 83.8°F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.2 Regional and Local Geologic Setting

The central and northern portions of the Plant, including the East BAP, are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 "*Ground-Water Resources of Harrison County, Texas*" (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology "*Geologic Atlas of Texas – Tyler Sheet*" (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K "*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*" (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled "*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*" (ETTL, 2010).

2.4.3 Surface Water and Surface Water Groundwater Interactions

Figure 9 is a potentiometric surface map based on January 2016 water level data for the uppermost water bearing unit at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1**. As shown on **Figure 9**, shallow groundwater flow direction in the area of the East BAP is west-southwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The East BAP is located approximately 2,000 feet north-northwest of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980's. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figure 9**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore shallow groundwater in the area of the East BAP does not discharge into Brandy Branch Reservoir. Brandy Branch Reservoir likely recharges the uppermost water bearing unit in the southern portion of the Plant, where the pool level in the Reservoir (340 feet amsl) is higher than water level elevations in monitoring wells located southwest (downslope) of the Reservoir.

2.4.4 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled approximately 500 feet south (side gradient) of the East BAP in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 350 to 430 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled approximately ¼-mile southwest (downgradient) of the East BAP for NFR Energy in 2008 for use as a rig supply well. The water well was screened from 250 to 310 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth, and is located approximately ¼-mile east (up gradient) of the Pirkey Power Plant.

3. Isolation from the Uppermost Aquifer

CCR Rule 40 CFR Part 257.60 requires that the base of new and existing CCR surface impoundments be constructed such that the base of the unit is no less than 5 ft above the top of the uppermost aquifer, or that if the base is within 5 ft of the uppermost aquifer, that there will not be hydraulic connection between the base of the unit and the uppermost aquifer.

3.1 Uppermost Aquifer and Piezometric Analysis

3.1.1 Piezometric Analysis

3.1.1.1 Horizontal and Vertical Position Relative to CCR Unit

Geologic data from soil borings, piezometers, and monitoring wells installed at the Site show the uppermost water bearing unit in the area of the East BAP is a very fine to fine grained clayey and silty sand stratum with an average thickness of approximately 15 feet that is located between an elevation of approximately 325 and 340 feet amsl (**Appendix A**). The base of the East BAP is at an elevation of 347 feet amsl. Therefore the separation distance between the uppermost water-bearing unit and the base of the East BAP is approximately seven feet. This separation distance is further illustrated on cross section A-A' (**Figure 4)** and cross section E-E' (**Figure 8**).

3.1.1.2 Overall Flow Conditions

Groundwater is recharged from regional precipitation infiltration. The uppermost water bearing unit (clayey and silty sand) is expected to have a hydraulic conductivity of approximately 10^{-4} centimeters per second (Fetter, 1980). Based on the hydraulic conductivity and saturated thickness (approximately 15 feet), the yield of the uppermost water-bearing unit is anticipated to exceed the TCEQ non-useable (Class 3) limit of 150 gallons per day (TCEQ, 2010).

Available groundwater elevations are summarized on **Table 1** for 2011 through 2016. The most recent comprehensive groundwater data set from January 2016 is depicted on **Figure 9**. The groundwater flow is west-southwesterly towards Hatley Creek, which is located approximately one mile west of the Site.

3.1.2 Uppermost Aquifer

3.1.2.1 CCR Rule Definition

The CCR rule definitions for an aquifer and the uppermost aquifer as specified in 40 CFR 257.53 indicates an aquifer is a geologic formation capable of yielding usable quantities of groundwater to wells or springs while an uppermost aquifer is defined as the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers, that are hydraulically interconnected with this aquifer within the facility's property boundary. Upper limit is measured at a point nearest to the natural groundwater surface to which the aquifer rises during the wet season.

3.1.2.2 Common definitions

An aquifer is commonly defined as a geologic unit that stores and transmits water (readily or at sufficient flow rates) to supply wells and springs (USGS, 2015; Fetter, 2001). The uppermost aquifer is considered the first encountered aquifer nearest to the CCR unit.

3.1.3 Identified onsite hydrostratigraphic unit

The identified Site hydrostratigraphic unit in the area of the East BAP is the clayey and silty sand stratum that is located between an elevation of approximately 325 and 340 feet amsl.

3.2 Compliance with Isolation Distance

The uppermost water-bearing unit underlying the East BAP meets the regulatory definition of an aquifer. As shown on the cross-sections presented on **Figures 4** and **8**, the base of the East BAP is six feet or more above this aquifer. Therefore, this CCR Unit complies with the requirement for placement above the uppermost aquifer. Also, four soil borings (S-4 through S-7) were advanced six feet below the base of the East BAP in 1983 following installation of the clay liner, and these four soil borings confirm the presence of the clay liner below the East BAP.

4. Wetlands

CCR Rule 40 CFR Part 257.61 requires that existing and new CCR surface impoundments must not be located in wetlands.

4.1 Local Wetlands

Based on the August 19, 2015 site visit and review of available published information, the East BAP is not located within an area that exhibited wetland characteristics that might be classified as a regulated wetland. Photos of the East BAP area are included in **Appendix B**, and **Figure 10** is a map showing wetlands locations in the CCR unit area.

4.2 Compliance with Wetland Restrictions

Based on the August 19, 2015 site visit and review of available information, the East BAP does not contain wetlands. Therefore, this CCR Unit complies with the requirement for not being located in a wetlands.

5. Fault Areas

CCR Rule 40 CFR Part 257.62 requires that existing and new CCR surface impoundments must not be located within 200 feet of the outermost damage zone of a fault that has had displacement in Holocene time unless the owner or operator demonstrates that an alternate setback will prevent damage to the structural integrity of the CCR unit.

5.1 Description of Regional Geologic Structural Features

Regional geologic publications were reviewed to determine structural features for the Site. A regional fault map is provided on **Figure 11**. The U.S. Geological Survey Open File Report 88-450K shows the Site is located within the East Texas Basin, with faulting north of the basin (Talco Fault Zone) and south of the basin (Elkhart-Mt. Enterprise Fault Zone). No faulting was identified in the Site area (USGS, 1988). Texas Water Development Board Report 27, and the University of Texas at Austin Bureau of Economic Geology Geologic Atlas of Texas – Tyler Sheet show no faulting at the Site (Broom, 1966; Flawn, 1965).

A previous evaluation of geologic structural features at the Site was conducted by ETTL, and no evidence of faulting was identified (ETTL, 2010).

5.2 Compliance with Fault Area Restrictions

A review of available geologic reports and maps has indicated that the Site is not located near any faults with displacement in the Holocene. Therefore, the CCR unit complies with the requirement for not being located within 200 feet of the outermost damage zone of a fault that has had displacement in Holocene time.

6. Seismic Impact Zone

CCR Rule 40 CFR Part 257.63 requires that existing and new CCR surface impoundments must not be located within a seismic impact zone unless the owner or operator demonstrates that all structural components of the CCR unit are designed to withstand the maximum horizontal acceleration in lithified earth material for the site.

6.1 Definition of Seismic Impact Zone

CCR Rule 40 CFR Part 257.53 defines a seismic impact zone as an area having a 2% or greater probability that the maximum horizontal acceleration expressed as a percentage of the earth's gravitational pull (g) will exceed 0.10 g in 50 years.

6.2 Compliance with Seismic Impact Zone Restriction

Figure 12 presents the seismic hazard map for Texas, as published by the USGS. As shown on **Figure 12**, the Site falls within the zone having a maximum horizontal acceleration of 0.04 to 0.06 g. Therefore, the CCR unit complies with the requirement for not being located in a seismic impact zone.

7. Unstable Areas

CCR Rule 40 CFR Part 257.64 requires that existing and new CCR surface impoundments must not be located within an unstable area unless the owner or operator demonstrates that the design of the unit will ensure the integrity of the structural components of the unit.

7.1 Definition of Unstable Area and local Conditions

7.1.1 CCR Rule Definition

CCR Rule 40 CFR Part 257.53 defines an unstable area as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of the CCR unit. These may include poor foundation conditions, areas susceptible to mass movements (landslides), and karst terrains.

7.1.2 Poor Foundation Soils

The East BAP design report was prepared by Sargent & Lundy in 1983 (Sargent & Lundy, 1983). The East BAP was constructed in 1983 using compacted clay. The specifications included installation of clay embankments with 3:1 slopes (3 feet horizontal, 1 foot vertical) around the perimeter of the pond with a crest (top of embankment) elevation of 357 feet amsl, and compaction of the clay embankments to ≥95% standard proctor density. The specifications also included emplacement of a compacted cohesive clay lining below the pond base elevation of 347 feet amsl.

ETTL conducted a geotechnical investigation of the East BAP earthen embankment in 2009. The investigation included installation of two soil borings through the embankment (E1, E2), completion of the soil borings as piezometers PE-1 and PE-2, respectively, and collection of soil samples for geotechnical analyses. The report noted the East BAP was cut (incised) into native soils with minimal embankment heights. The report concluded the embankment was stable and the existing embankment slopes were acceptable if conditions are maintained (ETTL, 2010). The conditions to be maintained included embankment protection from erosion (vegetative cover), removal of brush and trees two feet or more in height, and control of animal burrowing.

7.1.3 Mass Movements

The East BAP is not located within an area subject to mass movements. This conclusion is supported by the ETTL soil stability report (ETTL, 2010).

7.1.4 Karst

The site area is located on the outcrop of unconsolidated Cretaceous Formations consisting predominantly of sand and clay (Broom, 1966; Flawn, 1965). The East BAP is not located in a karst area.

7.1.5 Subsurface Mining

No subsurface mines are known to exist below the CCR units at the Site.

7.2 Compliance with Unstable Areas Restriction

Based on our site visit and review of available information, the East BAP is not located within unstable areas. Therefore, this CCR unit complies with the requirement of not being located in an unstable area.

8. Summary, Conclusions, and PE Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, as well as the evaluations discussed within this report, the H.W. Pirkey Power Plant East Bottom Ash Pond complies with the requirements of the location restrictions sections of 40 CFR 257 Subpart D that apply to surface impoundments and therefore the CCR unit is not located in a restricted location.

1. Objective

This report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to assess the location of the West Bottom Ash Pond (BAP) relative to the location restrictions included in the Coal Combustion Residual (CCR) requirements, as specified in the Code of Federal Regulations (CFR) 40 CFR 257.60 to 257.64, at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The CCR requirements include an evaluation of the adequacy of the groundwater monitoring well network to characterize groundwater quality up and down gradient of the CCR unit and an evaluation of whether the CCR unit meets up to 5 location restrictions, which include: the base of the CCR unit is 5 feet (ft) above the uppermost aquifer, the CCR unit may not be located in a wetland, within 200 ft of the damage zone of a fault that has displacement during the Holocene, within a seismic impact zones, or in an unstable area.

Four regulated CCR units associated with the Plant were identified for review, which include the West BAP, East BAP, Stack Out Area, and Landfill (**Figure 2**). This report summarizes the evaluation of the location restriction criteria at the West BAP (Site). The evaluation of the groundwater monitoring well network in the uppermost aquifer for the West BAP is not included in this report and will be completed under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the West BAP CCR unit, as well as publically-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on documents reviewed and will further describe the uppermost aquifer.

2. Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant West BAP.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The West BAP CCR unit is located at the north end of the Plant and approximately 3,000 feet northwest of Brandy Branch Reservoir (**Figures 1** and **2**).

2.2 Description of West BAP CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the West BAP.

2.2.1 Embankment Configuration

The West BAP embankments have a maximum height of approximately 25 feet and are constructed of compacted clay on a slope ranging from 2.5:1 (2.5 feet horizontal, 1 foot vertical) to 3:1 (Sargent & Lundy, 1983). The elevation at the top of the embankment around the perimeter of the West BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, 2011). The interior bottom elevation of the West BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Akron Consulting, 2012).

2.2.2 Area/Volume

The West BAP is approximately 30.9 acres in size. The design maximum ash storage capacity of the West BAP is 188 acre feet at an elevation of 354 feet amsl (normal operating level) and 216.5 acre feet at an elevation of 355 feet amsl (maximum operating level) (Sargent & Lundy, 1983; Akron Consulting, 2012).

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant West BAP was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, flue gas desulfurization sludge) have been generated. The West BAP, which was placed into operation in 1985, receives bottom ash and economizer ash sluiced from the power plant boiler (**Figure 3**). Clear water overflow from the West BAP discharges into the Clearwater Pond located southeast of the West

BAP. Bottom ash and economizer ash are periodically excavated from the West BAP and hauled by truck to either the on-site landfill for disposal, or for beneficial re-use.

The base of the West BAP was constructed in 1983 with a compacted clay liner (Sargent & Lundy, 1983). Following installation of the compacted clay liner, soil borings S-8 through S-11 were advanced below the base of the West BAP to total depths of six feet in September 1983 (Southwestern Laboratories, 1984). The lithologic data from soil borings S-8 through S-11 confirm at least six feet of clay is present below the base of the West BAP (Sargent & Lundy, 1984).

2.2.4 Surface Water Control

Surface water elevation in the West BAP is controlled by a weir box and a manually operated gate valve on a 36-inch-diameter discharge pipe at the southeast corner of the pond. Clear water overflow from the West BAP discharges through the 36-inch-diameter pipe into the 2.7- acre Clearwater Pond located southeast of the West BAP (Figure 3). Water in the Clearwater Pond is either pumped (re-circulated) back into the boiler ash hopper, or gravity discharged through a pipe at the southwest corner of the Clearwater Pond into an unnamed intermittent tributary of Hatley Creek via Outfall 006 in accordance with Texas Pollutant Discharge Elimination System (TPDES) Permit No. WQ0002496000.

2.3 Previous Investigations

The initial soils investigation and design of the West BAP was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, and design of the West BAP. As discussed above in Section 2.2.3, the design included installation of a clay liner below the West BAP.

In September-October 1983, Southwestern Laboratories conducted a soil investigation at the Plant, including advancement of four soil borings (S-8 through S-11) below the West BAP (Southwestern Laboratories, 1984).

In 1984, Sargent & Lundy conducted an evaluation of the West BAP. This report included evaluation of soil sample geotechnical data, and concluded a low-permeability clay liner was present below the West BAP (Sargent & Lundy, 1984).

In 2009, ETTL Engineers & Consultants (ETTL) conducted a geotechnical investigation of the West BAP earthen embankment. The investigation included installation of two soil borings through the embankment (W1, W3) and two soil borings along the outer toe of the embankment (W2, W4), completion of soil borings W1 and W3 as piezometers PW-1 and PW-3, respectively, and collection of soil samples for geotechnical analyses. The report concluded the embankment was stable and the existing embankment slopes were acceptable if conditions are maintained (ETTL, 2010). The conditions to be maintained included embankment protection from erosion (vegetative cover), removal of brush and trees two feet or more in height, and control of animal burrowing.

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, 2011).

In 2011, Johnson & Pace performed a hydraulic analysis of the West BAP for a 10-year, 24-hour rainfall event in accordance with the TCEQ TPDES permit design criteria. The report concluded the storage capacity of the West BAP is hydraulically adequate (Johnson & Pace, 2011).

In 2015, Auckland Consulting further expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-30 through AD-35 (Auckland Consulting, 2016).

2.4 Hydrogeologic Setting

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Plant. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of approximately 100 feet (Broom, 1966).

These features are further illustrated on five lines of cross section that were prepared through the West BAP area, with three lines trending from west to east (A-A'; B-B'; C-C'), and the other two lines trending from north to south (D-D'; E-E'). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure** 4 (A-A') through **Figure 8** (E-E').

2.4.1 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1° Fahrenheit (F) in January to 83.8°F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.2 Regional and Local Geologic Setting

The central and northern portions of the Plant, including the West BAP, are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 "*Ground-Water Resources of Harrison County, Texas*" (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology "*Geologic Atlas of Texas – Tyler Sheet*" (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K "*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*" (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled "*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*" (ETTL, 2010).

2.4.3 Surface Water and Surface Water Groundwater Interactions

Figure 9 is a potentiometric surface map based on January 2016 water level data for the uppermost water bearing unit at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1**. As shown on **Figure 9**, shallow groundwater flow direction in the area of the West BAP is west-southwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The West BAP is located approximately 3,000 feet northwest of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980's. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figure 9**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore shallow groundwater in the area of the West BAP does not discharge into Brandy Branch Reservoir. Brandy Branch Reservoir likely recharges the uppermost water bearing unit in the southern portion of the Plant, where the pool level in the Reservoir (340 feet amsl) is higher than water level elevations in monitoring wells located southwest (downslope) of the Reservoir.

2.4.4 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled approximately 500 feet southeast (sidegradient) of the West BAP in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 350 to 430 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled approximately ¼-mile south (side gradient) of the West BAP for NFR Energy in 2008 for use as a rig supply well. The water well was screened from 250 to 310 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth, and is located approximately ¼-mile east (up gradient) of the Pirkey Power Plant.

3. Isolation from the Uppermost Aquifer

CCR Rule 40 CFR Part 257.60 requires that the base of new and existing CCR surface impoundments be constructed such that the base of the unit is no less than 5 ft above the top of the uppermost aquifer, or that if the base is within 5 ft of the uppermost aquifer, that there will not be hydraulic connection between the base of the unit and the uppermost aquifer.

3.1 Uppermost Aquifer and Piezometric Analysis

3.1.1 Piezometric Analysis

3.1.1.1 Horizontal and Vertical Position Relative to CCR Unit

Geologic data from soil borings, piezometers, and monitoring wells installed at the Site show the uppermost water bearing unit in the area of the West BAP is a very fine to fine grained clayey and silty sand stratum with an average thickness of approximately 15 feet that is located between an elevation of approximately 325 and 340 feet amsl (**Appendix A**). The base of the West BAP is at an elevation of 347 feet amsl. Therefore the separation distance between the uppermost water-bearing unit and the base of the West BAP is approximately seven feet. This separation distance is further illustrated on cross section A-A' (**Figure 4)** and cross section D-D' (**Figure 7**).

3.1.1.2 Overall Flow Conditions

Groundwater is recharged from regional precipitation infiltration. The uppermost water bearing unit (clayey and silty sand) is expected to have a hydraulic conductivity of approximately 10^{-4} centimeters per second (Fetter, 1980). Based on the hydraulic conductivity and saturated thickness (approximately 15 feet), the yield of the uppermost water-bearing unit is anticipated to exceed the TCEQ non-useable (Class 3) limit of 150 gallons per day (TCEQ, 2010).

Available groundwater elevations are summarized on **Table 1** for 2011 through 2016. The most recent comprehensive groundwater data set from January 2016 is depicted on **Figure 9**. The groundwater flow is west-southwesterly towards Hatley Creek, which is located approximately one mile west of the Site.

3.1.2 Uppermost Aquifer

3.1.2.1 CCR Rule Definition

The CCR rule definitions for an aquifer and the uppermost aquifer as specified in 40 CFR 257.53 indicates an aquifer is a geologic formation capable of yielding usable quantities of groundwater to wells or springs while an uppermost aquifer is defined as the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers, that are hydraulically interconnected with this aquifer within the facility's property boundary. Upper limit is measured at a point nearest to the natural groundwater surface to which the aquifer rises during the wet season.

3.1.2.2 Common definitions

An aquifer is commonly defined as a geologic unit that stores and transmits water (readily or at sufficient flow rates) to supply wells and springs (USGS, 2015; Fetter, 2001). The uppermost aquifer is considered the first encountered aquifer nearest to the CCR unit.

3.1.3 Identified onsite hydrostratigraphic unit

The identified Site hydrostratigraphic unit in the area of the West BAP is the clayey and silty sand stratum that is located between an elevation of approximately 325 and 340 feet amsl.

3.2 Compliance with Isolation Distance

The uppermost water-bearing unit underlying the West BAP meets the regulatory definition of an aquifer. As shown on the cross-sections presented on **Figures 4** and **7**, the base of the West BAP is seven feet or more above this aquifer. Therefore, this CCR Unit complies with the requirement for placement above the uppermost aquifer. Also, four soil borings (S-8 through S-11) were advanced six feet below the base of the West BAP in 1983 following installation of the clay liner, and these four soil borings confirm the presence of the clay liner below the West BAP.

4. Wetlands

CCR Rule 40 CFR Part 257.61 requires that existing and new CCR surface impoundments must not be located in wetlands.

4.1 Local Wetlands

Based on the August 19, 2015 site visit and review of available published information, the West BAP is not located within an area that exhibited wetland characteristics that might be classified as a regulated wetland. Photos of the West BAP area are included in **Appendix B**, and **Figure 10** is a map showing wetlands locations in the CCR unit area.

4.2 Compliance with Wetland Restrictions

Based on the August 19, 2015 site visit and review of available information, the West BAP does not contain wetlands. Therefore, this CCR Unit complies with the requirement for not being located in a wetlands.

5. Fault Areas

CCR Rule 40 CFR Part 257.62 requires that existing and new CCR surface impoundments must not be located within 200 feet of the outermost damage zone of a fault that has had displacement in Holocene time unless the owner or operator demonstrates that an alternate setback will prevent damage to the structural integrity of the CCR unit.

5.1 Description of Regional Geologic Structural Features

Regional geologic publications were reviewed to determine structural features for the Site. A regional fault map is provided on **Figure 11**. The U.S. Geological Survey (USGS) Open File Report 88-450K shows the Site is located within the East Texas Basin, with faulting north of the basin (Talco Fault Zone) and south of the basin (Elkhart-Mt. Enterprise Fault Zone). No faulting was identified in the Site area (USGS, 1988). Texas Water Development Board Report 27 and the University of Texas at Austin Bureau of Economic Geology Geologic Atlas of Texas – Tyler Sheet show no faulting at the Site (Broom, 1966; Flawn, 1965).

A previous evaluation of geologic structural features at the Site was conducted by ETTL, and no evidence of faulting was identified (ETTL, 2010).

5.2 Compliance with Fault Area Restrictions

A review of available geologic reports and maps has indicated that the Site is not located near any faults with displacement in the Holocene. Therefore, the CCR unit complies with the requirement for not being located within 200 feet of the outermost damage zone of a fault that has had displacement in Holocene time.

6. Seismic Impact Zone

CCR Rule 40 CFR Part 257.63 requires that existing and new CCR surface impoundments must not be located within a seismic impact zone unless the owner or operator demonstrates that all structural components of the CCR unit are designed to withstand the maximum horizontal acceleration in lithified earth material for the site.

6.1 Definition of Seismic Impact Zone

CCR Rule 40 CFR Part 257.53 defines a seismic impact zone as an area having a 2% or greater probability that the maximum horizontal acceleration expressed as a percentage of the earth's gravitational pull (g) will exceed 0.10 g in 50 years.

6.2 Compliance with Seismic Impact Zone Restriction

Figure 12 presents the seismic hazard map for Texas, as published by the USGS. As shown on **Figure 12**, the Site falls within the zone having a maximum horizontal acceleration of 0.04 to 0.06 g. Therefore, the CCR unit complies with the requirement for not being located within a seismic impact zone.

7. Unstable Areas

CCR Rule 40 CFR Part 257.64 requires that existing and new CCR surface impoundments must not be located within an unstable area unless the owner or operator demonstrates that the design of the unit will ensure the integrity of the structural components of the unit.

7.1 Definition of Unstable Area and local Conditions

7.1.1 CCR Rule Definition

CCR Rule 40 CFR Part 257.53 defines an unstable area as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of the CCR unit. These may include poor foundation conditions, areas susceptible to mass movements (landslides), and karst terrains.

7.1.2 Poor Foundation Soils

The West BAP design report was prepared by Sargent & Lundy in 1983 (Sargent & Lundy, 1983). The West BAP was constructed in 1983 using compacted clay. The specifications included installation of clay embankments around the perimeter of the pond with a crest (top of embankment) elevation of 357 feet amsl, and compaction of the clay embankments to ≥95% standard proctor density. The specifications also included emplacement of a compacted cohesive clay lining below the pond base elevation of 347 feet amsl.

ETTL conducted a geotechnical investigation of the West BAP earthen embankment in 2009. The investigation included installation of two soil borings through the embankment (W1, W3) and two soil borings along the outer toe of the embankment (W2, W4), completion of soil borings W1 and W3 as piezometers PW-1 and PW-3, respectively, and collection of soil samples for geotechnical analyses. The report concluded the embankment was constructed with layers of cohesive soils consisting primarily of lean clay and/or fat clay with no obvious seams of soft or loose soils, and the embankment was stable and the existing embankment slopes were acceptable if conditions are maintained (ETTL, 2010). The conditions to be maintained included embankment protection from erosion (vegetative cover), removal of brush and trees two feet or more in height, and control of animal burrowing.

7.1.3 Mass Movements

The West BAP is not located within an area subject to mass movements. This conclusion is supported by the ETTL soil stability report (ETTL, 2010).

7.1.4 Karst

The site area is located on the outcrop of unconsolidated Cretaceous Formations consisting predominantly of sand and clay (Broom, 1966; Flawn, 1965). The West BAP is not located in a karst area.

7.1.5 Subsurface Mining

No subsurface mines are known to exist below the CCR units at the Site.

7.2 Compliance with Unstable Areas Restriction

Based on our site visit and review of available information, the West BAP is not located within unstable areas. Therefore, this CCR unit complies with the requirement of not being located within an unstable area.

8. Summary, Conclusions, and PE Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, as well as the evaluations discussed within this report, the H.W. Pirkey Power Plant West Bottom Ash Pond complies with the requirements of the location restrictions sections of 40 CFR 257 Subpart D that apply to surface impoundments and therefore the CCR unit is not located in a restricted location.

Acronyms and Abbreviation

AEP	American Electric Power Service Cooperation
amsl	above mean sea level
ARCADIS	ARCADIS U.S., Inc.
BAP	bottom ash pond
BGL	below ground surface
CCR	Coal Combustion Residual
CFR	Code of Federal Regulations

EPRI	Electric Power Research Institute
FAP	fly ash pond
FGD	flue gas desulfurization
ft	feet
PTI	Permit to Install
TAC	Texas Administrative Code
TCEQ	Texas Commission on Environmental Quality

1. Objective

This report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to assess the location of the 2018 Lateral Expansion of the existing on-site Landfill relative to the location restrictions included in the Coal Combustion Residual (CCR) requirements, as specified in the Code of Federal Regulations (CFR) 40 CFR 257.60 to 257.64, at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The CCR requirements include an evaluation of the adequacy of the groundwater monitoring well network to characterize groundwater quality up and down gradient of the CCR unit and an evaluation of whether the CCR unit meets up to 5 location restrictions, which include: the base of the CCR unit is 5 feet (ft) above the uppermost aquifer, the CCR unit may not be located in a wetland, within 200 ft of the damage zone of a fault that has displacement during the Holocene, within a seismic impact zone, or in an unstable area.

Four regulated CCR units associated with the Plant were identified for review, which include the West Bottom Ash Pond (BAP), East BAP, Stack Out Area, and Landfill (**Figure 2**). The initial CCR Location Restriction Evaluation for the existing Landfill was prepared in 2016 (Arcadis, 2016). This report has been prepared for the 2018 Lateral Expansion of the existing Landfill (Site) and includes an updated evaluation of the location restriction criteria. The evaluation of the groundwater monitoring well network in the uppermost aquifer for the 2018 Lateral Expansion of the existing Landfill is not included in this report and will be completed under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the Landfill CCR unit, as well as publicly-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on documents reviewed and will further describe the uppermost aquifer.

2. Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant Landfill.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas (**Figure 1**). The existing Landfill CCR unit is currently approximately 130 acres in size and is located in the southern portion of the Plant. The 2018 Landfill Lateral Expansion will cover approximately 15 acres directly south of the existing Landfill (**Figures 2** and **3**). Following completion of the 2018 Lateral Expansion, the Landfill will be approximately 145 acres in size.

2.2 Description of Landfill CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the Landfill.

2.2.1 Embankment Configuration

The Landfill was constructed in the southwestern portion of the Plant, and as shown on the U.S. Geological Survey 1983 topographic map (**Figure 1**), the southwestern portion of the Plant contained an unnamed intermittent tributary of Hatley Creek prior to Landfill construction in 1984. The Landfill was constructed within the unnamed tributary creek which had a bottom elevation ranging from approximately 290 feet amsl on the south side of the Landfill to 300 feet amsl on the north side of the Landfill. The native soil sidewalls of the tributary creek at the Landfill location have a maximum elevation of approximately 355 feet amsl. Therefore, as shown on Geologic Cross Section C-C' (**Figure 6**), the Landfill is partially incised within the tributary creek, and the tributary creek native soil sidewalls serve as a natural embankment for the lower portion of the Landfill.

The original Landfill design included emplacement of CCR materials in the Landfill with 3:1 slopes (3 feet horizontal, 1 foot vertical) with an approximate 10 foot wide bench for every 20 foot vertical rise of CCR material (VFL Technology Corporation, 1984). Apex Geoscience conducted a geotechnical investigation of the Landfill CCR materials in 2012, and concluded the CCR material embankments would be stable on 3:1 slopes (Apex Geoscience, 2013).

In addition to the Landfill CCR material embankments, earthen embankments are present around portions of the Landfill to control storm water flow. The earthen embankments are constructed using compacted clay on 3:1 slopes. ETTL Engineers & Consultants Inc (ETTL) conducted a geotechnical evaluation of the perimeter embankments in 2005 and concluded the perimeter embankments would be stable on slopes no steeper than 3:1 unless the slopes are stabilized with geogrid reinforcement (ETTL, 2005).

The Landfill Stormwater Runoff Pond (non-CCR Unit) was constructed downslope (south) of the Landfill in 1993 and 1994. The Landfill Stormwater Runoff Pond has perimeter compacted soil embankments up to approximately 19 feet in height. Apex Geoscience conducted a geotechnical investigation of the Landfill Stormwater Runoff Pond embankments in 2011. Apex Geoscience recommended raising the elevation of the Landfill Stormwater Runoff Pond embankments to an elevation of 302 feet amsl using soils compacted to at least 95% standard proctor density, with an emergency spillway at a crest elevation of 298 feet amsl. The Apex Geoscience report concluded the Landfill Stormwater Runoff Pond embankments would be stable (Apex Geoscience, April 2011).

The 2018 Landfill Lateral Expansion will cover approximately 15 acres directly south of the existing Landfill. In 2016, Auckland Consulting conducted a stability assessment of the 2018 Lateral Expansion area and concluded the embankments would be stable on slopes no steeper than 3:1 (Auckland, November 2016). The 2016 Auckland Consulting report stated the northern and eastern extents of the 2018 Lateral Expansion will be constructed contiguous to the existing Landfill disposal area, and ash disposal will be completed in multiple lifts, each with an approximate height of 20 feet, integrated with safety benches, and maximum side slopes of 3:1 to a maximum waste height of 120 feet.

2.2.2 Area/Volume

The existing Landfill is approximately 130 acres in size and was designed to receive 12,207,000 cubic yards (7,566 acre feet) of CCR materials including fly ash, bottom ash, economizer ash, and stabilized FGD sludge (VFL Technology Corporation, 1984). The design maximum CCR material height in the existing Landfill is approximately 140 feet (Apex Geoscience, 2013). As discussed above in Section 2.2.1, the 2018 Landfill Lateral Expansion will cover an area of approximately 15 acres to a maximum waste height of 120 feet. The design capacity of the CCR materials to be placed within the 2018 Lateral Expansion is approximately 2,200,000 cubic yards.

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, stabilized FGD sludge) have been generated. The CCR materials that are not taken offsite for beneficial reuse are disposed of in the Landfill. The Landfill was constructed in several phases beginning with the northeast portion (Phase 1) in 1984. The Landfill was expanded (east-central portion) in 1985 and 1987. The Landfill was subsequently expanded to the west and south during the 1990's, including construction of the Landfill Stormwater Runoff Pond (non-CCR unit) directly south of the Landfill in 1993 and 1994. The Landfill was further expanded to the west between 2005 and 2015 to its current size of approximately 130 acres as shown on **Figure 3**.

In 2005, ETTL conducted a geotechnical evaluation of the Landfill and Landfill Stormwater Runoff Pond, including installation of 30 soil borings, ten cone penetration test (CPT) borings, and geotechnical testing of soil samples. The ETTL report concluded the Landfill CCR materials would be stable at 3:1 slopes; and foundation settlement would be within acceptable limits (ETTL, 2005). The ETTL report recommended that Landfill expansion activities include a composite liner system consisting of a 2-foot-thick compacted clay liner or geosynthetic clay liner (GCL) as the bottom component; and a top liner component consisting of a PVC, high-density polyethylene (HDPE), or a very low density polyethylene (VLDPE) liner. ETTL also recommended Landfill expansion activities include installation of a Landfill leachate collection system consisting of permeable bottom ash emplaced above the Landfill liner. These recommendations were implemented during Landfill expansion phases between 2005 and 2015.

The 2018 Landfill Lateral Expansion design includes emplacement of up to 120 feet of CCR materials with maximum side slopes of 3:1 above the Landfill liner system which will consist of a 60-mil HDPE top liner underlain by a 2-foot-thick compacted clay bottom liner. Prior to installation of the liner system, approximately 10 to 15 feet of cut into the existing soils will occur along the topographically higher southern portion of the Lateral Expansion, and emplacement of these soils (clayey sands, silty clayey sand and/or lean clays) as fill materials below the liner system in the topographically lower central and northern portions of the Lateral Expansion. As detailed below in Section 3, the fill materials emplaced in the topographically lower portions of the Lateral Expansion will extend in height at least five feet above the water table, thereby providing the required separation distance of at least five feet between the base of the CCR unit and the top of the uppermost aquifer.

2.2.4 Surface Water Control

Surface water in the area of the existing Landfill flows in a general southerly direction to the Landfill Stormwater Runoff Pond located directly southwest of the existing Landfill. Surface water in the area of the 2018 Landfill Lateral Expansion flows in a general westerly direction to the Landfill Stormwater Runoff Pond. The Landfill Stormwater Runoff Pond, which is approximately 16 acres in size, also receives (1) Landfill leachate that is gravity drained from the existing Landfill via underground lateral perforated pipes and permeable bottom ash materials that were installed above portions of the existing Landfill liner, (2) Landfill leachate that will gravity drain via underground lateral perforated pipes that will be installed above the 2018 Landfill Lateral Expansion liner system, and (3) shallow groundwater that will gravity drain via underground lateral perforated HDPE underdrain pipes that will be installed in permeable bottom ash materials approximately seven feet below the 60-mil HDPE liner of the 2018 Landfill Lateral Expansion.

An emergency spillway is present at the southern end of the Landfill Stormwater Runoff Pond at an elevation of approximately 298 feet amsl. The top of the Landfill Stormwater Runoff Pond is located at an elevation of approximately 302 feet amsl, therefore the Landfill Stormwater Runoff Pond has approximately four feet of freeboard (Apex Geoscience, April 2011). Water in the Landfill Stormwater Runoff Pond discharges into an unnamed intermittent tributary of Hatley Creek via Outfall 004 in accordance with Texas Pollutant Discharge Elimination System (TPDES) Permit No. WQ0002496000.

2.3 Previous Investigations

The initial soils investigation and design of the Plant was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, including the Landfill Area.

A soils investigation of the Landfill was conducted by Southwestern Laboratories in 1984. The investigation included installation of 45 soil borings and geotechnical analyses of soil samples. The report recommended installation of three feet of compacted clay as the bottom liner for the Landfill (Southwestern Laboratories, July 1984).

An engineering design report for the Landfill was prepared by VFL Technology Corporation in 1984. The Landfill design included a bottom compacted clay liner three feet in thickness, and Landfill side slopes of 3:1 (VFL Technology Corporation, 1984).

In 1985, Southwestern Laboratories conducted a geotechnical evaluation of the clay liner that was installed at the base of the Landfill, including installation of four soil borings and permeability testing of soil samples. The report concluded the clay liner was three feet thick with a permeability less than 1×10^{-7} centimeters per second (cm/sec) (Southwestern Laboratories, 1985).

In 1993, Alliance Inc. conducted a geotechnical investigation of the clay liner installed at the base of the Landfill following a Landfill expansion phase in 1993. The report concluded the clay liner was three feet or more in thickness, and the clay liner met the permeability specifications of $<1 \times 10^{-7}$ cm/sec (Alliance Inc., 1993).

In 1995, Central and South West Services prepared design specifications for Landfill expansion to the west and south. The design specifications included a geosynthetic clay liner overlain by a 0.060 inch (60 mil) HDPE liner (Central and South West Services, 1995).

In 2005, ETTL conducted a geotechnical evaluation of the Landfill and Landfill Stormwater Runoff Pond, including installation of 30 soil borings, ten CPT borings, and geotechnical testing of soil samples. The geotechnical data was obtained to design Landfill expansions in 2005 through 2007. The ETTL report concluded the Landfill CCR materials would be stable at 3:1 slopes; and foundation settlement would be within acceptable limits (ETTL, 2005). The ETTL report recommended the Landfill expansion include a composite liner system consisting of a 2-foot-thick compacted clay liner or GCL as the bottom component; and a top liner component consisting of a PVC, HDPE, or a VLDPE liner. ETTL also recommended the Landfill expansion include a leachate collection system consisting of permeable bottom ash emplaced above the Landfill liner. These recommendations were implemented during Landfill expansion phases between 2005 and 2015.

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, March 2011).

In 2011, Apex Geoscience conducted a geotechnical investigation of the Landfill Stormwater Runoff Pond. The report recommended raising the elevation of the Landfill Stormwater Runoff Pond embankments to an elevation of 302 feet amsl using soils compacted to at least 95% standard proctor density, and an emergency spillway with a crest elevation of 298 feet amsl (Apex Geoscience, April 2011). These recommendations were implemented during subsequent Landfill Stormwater Runoff Pond construction activities.

In 2012, Apex Geoscience conducted a geotechnical investigation for Landfill expansion activities at the western portion of the Landfill where surface lignite mining operations had previously been conducted to a depth of 50 to 100 feet using a dragline, and the spoils (reclaimed soil) were returned to the excavation. The report concluded the Landfill embankments would be stable with side slopes of 3:1 (Apex Geoscience, 2013).

In 2015, Auckland Consulting further expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-30 through AD-35 (Auckland Consulting, 2016).

In 2016, Auckland Consulting conducted a geotechnical evaluation of the 2018 Landfill Lateral Expansion area, including installation of eight soil borings (B1 through B8) with total depths ranging from 40 to 62 feet below ground level (bgl). Soil boring locations are shown on **Figure 11**, and copies of the soil boring logs are provided in **Appendix C.** Based on the results of the 2016 geotechnical evaluation, including slope stability modeling and settlement analysis, Auckland Consulting concluded the 2018 Landfill Lateral Expansion will be structurally stable with maximum side slopes of 3:1 to a maximum disposal height of 120 feet (Auckland, November 2016).

In 2018, Auckland Consulting installed seven piezometers (PZ-1 through PZ-7) within the 2018 Landfill Lateral Expansion area to obtain detailed depth to groundwater and groundwater flow direction data prior to construction of the Lateral Expansion. The piezometers were completed in the uppermost water-bearing unit with total depths ranging from 14 to 20 feet bgl. Piezometer locations are shown on **Figure 11**, and piezometer completion data is provided in **Appendix C.**

2.4 Hydrogeologic Setting

2.4.1 General

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Site in the area of the Landfill Stormwater Runoff Pond. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of up to approximately 100 feet in Harrison county, Texas (Broom, 1966). As shown on Geologic Cross Sections C-C’ (**Figure 6**) and D-D’ (**Figure 7**), a thick sand stratum is located below and adjacent to the Landfill between an elevation of approximately 270 feet and 330 feet amsl. This sand stratum likely corresponds to the Carrizo Sand based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

The Carrizo Sand is underlain by the Eocene-age Wilcox Formation, which outcrops in topographically low areas near the Sabine River to the south and southeast of the Plant (Flawn, 1965). The Wilcox Formation consists of interbedded sand and clay with seams of lignite and attains a thickness of approximately 700 feet (Broom, 1966). As shown on Geologic Cross Section D-D’ (**Figure 7**), a lignite seam was encountered below an elevation of approximately 270 feet amsl during drilling of monitoring well AD-24 at the south end of the Site. This lignite seam likely corresponds to the top of the Wilcox Formation based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

These features are further illustrated on five lines of cross section that were prepared through the existing Landfill Area, with three lines trending from west to east (A-A’; B-B’; C-C’), and the other two lines trending from north to south (D-D’; E-E’). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure 4** (A-A’) through **Figure 8** (E-E’).

2.4.2 2018 Landfill Lateral Expansion Area

Based on the hydrogeologic data obtained from soil borings, monitoring wells, and piezometers installed in the 2018 Landfill Lateral Expansion area, three lines of cross section were prepared through the 2018 Landfill Lateral Expansion area. The cross section location map is included as **Figure 11** and the lines of cross section are included as **Figure 12** (F-F'), **Figure 13** (G-G'), and **Figure 14** (H-H').

As shown on **Figures 12** through **14**, a reddish-brown to gray clayey and silty sand stratum is located below the Lateral Expansion area between an elevation of approximately 280 feet and 330 feet amsl. This sand stratum likely corresponds to the Carrizo Sand based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

As shown on **Figures 12** through **14**, a clay stratum with an average thickness of approximately 10 feet is located below the sand stratum, and a lignite seam is present below the clay stratum at an elevation of approximately 270 feet amsl. As discussed above in Section 2.4.1, this lignite seam likely corresponds to the top of the Wilcox Formation based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

2.4.3 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1˚ Fahrenheit (F) in January to 83.8˚F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.4 Regional and Local Geologic Setting

The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant where the existing Landfill, 2018 Landfill Lateral Expansion, and Landfill Stormwater Runoff Pond are located (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 "*Ground-Water Resources of Harrison County, Texas*" (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology "*Geologic Atlas of Texas – Tyler Sheet*" (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K "*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*" (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled "*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*" (ETTL, 2010).

2.4.5 Surface Water and Surface Water Groundwater Interactions

Figures 9 and **10** are potentiometric surface maps based on January 2016 and August 2017 water level data, respectively, for the uppermost water bearing unit at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1**. As shown on **Figures 9** and **10**, shallow groundwater flow direction in the Landfill area is southwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The Landfill is located approximately 400 feet west of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980's. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figures 9** and **10**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore shallow groundwater in the Landfill area does not discharge into Brandy Branch Reservoir. Brandy Branch Reservoir likely recharges the uppermost water bearing unit in the southern portion of the Site, where the pool level in the Reservoir (340 feet amsl) is higher than water level elevations in monitoring wells located southwest (downslope) of the Reservoir.

Figure 15 is a current potentiometric surface map for the 2018 Landfill Lateral Expansion area, and water level elevations for the 2018 Landfill Lateral Expansion area piezometers are summarized on **Table 2**. As shown on **Figure 15**, shallow groundwater flow direction in the 2018 Landfill Lateral Expansion area is westerly toward the Landfill Stormwater Runoff Pond at a hydraulic gradient of approximately 0.02 foot per foot. Water level elevations in the 2018 Landfill Lateral Expansion area piezometers are higher than the surface water elevation of the Landfill Stormwater Runoff Pond (approximately 298 feet amsl), which indicates shallow groundwater in the 2018 Landfill Lateral Expansion area discharges into the Landfill Stormwater Runoff Pond.

2.4.6 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled directly east of the Landfill in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 330 to 426 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled directly south of the Landfill by Amoco Production Company in 1991 for use as an oil field rig supply well. The water well was screened from 163 to 243 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The third closest water well was reportedly drilled approximately 200 feet southwest of the Landfill by Matador Operating in 2000 for use as an industrial well. The water well was screened from 340 to 420 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth, and is located approximately ¼-mile east (up gradient) of the Pirkey Power Plant.

3. Isolation from the Uppermost Aquifer

CCR Rule 40 CFR Part 257.60 requires that the base of new and existing CCR surface impoundments be constructed such that the base of the unit is no less than 5 ft above the top of the uppermost aquifer, or that if the base is within 5 ft of the uppermost aquifer, that there will not be hydraulic connection between the base of the unit and the uppermost aquifer.

3.1 Uppermost Aquifer and Piezometric Analysis

3.1.1 Piezometric Analysis

3.1.1.1 Horizontal and Vertical Position Relative to CCR Unit

Geologic data from soil borings, piezometers, and monitoring wells installed in the 2018 Landfill Lateral Expansion area show the uppermost aquifer is a reddish-brown to gray clayey and silty sand stratum located between an elevation of approximately 280 feet and 330 feet amsl. As shown on **Figure 15** and **Table 2**, this sand stratum is saturated at an elevation ranging from approximately 298 feet amsl (PZ-1) in the topographically low northwest portion of the Lateral Expansion area to approximately 320 feet amsl (AD-23) in the topographically high southeast portion of the Lateral Expansion area.

As discussed above in Section 2.2.3, the 2018 Landfill Lateral Expansion design includes a liner system which will consist of a 60-mil HDPE top liner underlain by a 2-foot-thick compacted clay bottom liner. Prior to installation of the liner system, approximately 10 to 15 feet of cut into the existing soils will occur along the topographically higher southern portion of the Lateral Expansion, and emplacement of these soils (clayey sands, silty clayey sand and/or lean clays) as fill materials below the liner system in the topographically lower central and northern portions of the Lateral Expansion. The fill materials emplaced in the topographically lower portions of the Lateral Expansion will extend in height at least five feet above the water table, thereby providing the required separation distance of at least five feet between the base of the CCR unit and the top of the uppermost aquifer. This separation distance is illustrated on **Figure 16** which shows the elevation of the HDPE liner at the base of the Lateral Expansion. The elevation of the HDPE liner in the topographically low northwest portion of the Lateral Expansion will range from approximately 311 to 314 feet amsl, which is more than five feet higher than the elevation of the piezometric surface in this area (approximately 298 to 304 feet amsl).

3.1.1.2 Overall Flow Conditions

Groundwater is recharged from regional precipitation infiltration. The uppermost water bearing unit (clayey and silty sand) is expected to have a hydraulic conductivity of approximately 1 x 10^{-4} cm/sec (Fetter, 1980). Based on the hydraulic conductivity and saturated thickness (approximately 20 to 30 feet), the yield of the uppermost water-bearing unit in the Lateral Expansion area is anticipated to exceed the TCEQ non-useable (Class 3) limit of 150 gallons per day (TCEQ, 2010).

Current groundwater elevations in the Lateral Expansion area are summarized on **Table 2**, and a recent piezometric surface map is depicted on **Figure 15**. The piezometric surface map is based on water level elevations measured on June 22, 2018 when water levels were high due to a recent rainfall event. The June 22, 2018 water level elevations are more than 5 feet below the planned Lateral Expansion HDPE liner elevation, indicating the base of the CCR unit is more than 5 feet above the uppermost aquifer.

3.1.2 Uppermost Aquifer

3.1.2.1 CCR Rule Definition

The CCR rule definitions for an aquifer and the uppermost aquifer as specified in 40 CFR 257.53 indicates an aquifer is a geologic formation capable of yielding usable quantities of groundwater to wells or springs while an uppermost aquifer is defined as the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers, that are hydraulically interconnected with this aquifer within the facility's property boundary. Upper limit is measured at a point nearest to the natural groundwater surface to which the aquifer rises during the wet season.

3.1.2.2 Common Definitions

An aquifer is commonly defined as a geologic unit that stores and transmits water (readily or at sufficient flow rates) to supply wells and springs (USGS, 2015; Fetter, 2001). The uppermost aquifer is considered the first encountered aquifer nearest to the CCR unit.

3.1.3 Identified Onsite Hydrostratigraphic Unit

The identified Site hydrostratigraphic unit in the area of the 2018 Landfill Lateral Expansion area is the reddish-brown to gray clayey and silty sand stratum located between an elevation of approximately 280 feet and 330 feet amsl.

3.2 Compliance with Isolation Distance

The uppermost water-bearing unit underlying the 2018 Landfill Lateral Expansion meets the regulatory definition of an aquifer. As shown on **Figure 16**, the HDPE liner below the base of the CCR unit will be more than 5 feet above this aquifer. Therefore, this CCR Unit complies with the requirement for placement above the uppermost aquifer. Also, underground lateral perforated HDPE underdrain pipes will be installed in permeable bottom ash materials approximately seven feet below the 60-mil HDPE liner of the 2018 Landfill Lateral Expansion. These undrains will collect shallow groundwater when the water table is seasonally high, and gravity drain the groundwater into the Landfill Stormwater Runoff Pond, which will maintain the separation distance of at least 5 feet below the base of the CCR unit.

4. Wetlands

CCR Rule 40 CFR Part 257.61 requires that new CCR Landfill Lateral Expansions not be located in wetlands.

4.1 Local Wetlands

Based on review of available published information, including the National Hydrography Dataset (NHD) and National Wetland Inventory (NWI) maps, there are no jurisdictional wetlands in the 2018 Landfill Lateral Expansion area (USFWS, 2018; USGS, 2018). The topographically low northwest portion of the Lateral Expansion area has no connections to jurisdictional waters of the U.S. (WOTUS) and is non-jurisdictional. **Figure 17** is a map showing wetlands locations in the CCR unit area.

4.2 Compliance with Wetland Restrictions

Based on review of available information, the 2018 Landfill Lateral Expansion area does not contain wetlands. Therefore, the 2018 Landfill Lateral Expansion complies with the requirement for not being located in a wetland.

5. Fault Areas

CCR Rule 40 CFR Part 257.62 requires that new CCR Landfill Lateral Expansions must not be located within 200 feet of the outermost damage zone of a fault that has had displacement in Holocene time unless the owner or operator demonstrates that an alternate setback will prevent damage to the structural integrity of the CCR unit.

5.1 Description of Regional Geologic Structural Features

Regional geologic publications were reviewed to determine structural features for the Site. A regional fault map is provided on **Figure 18**. The U.S. Geological Survey Open File Report 88-450K shows the Site is located within the East Texas Basin, with faulting north of the basin (Talco Fault Zone) and south of the basin (Elkhart-Mt. Enterprise Fault Zone). No faulting was identified in the Site area (USGS, 1988). Texas Water Development Board Report 27, and the University of Texas at Austin Bureau of Economic Geology Geologic Atlas of Texas – Tyler Sheet show no faulting at the Site (Broom, 1966; Flawn, 1965).

A previous evaluation of geologic structural features at the Site was conducted by ETTL, and no evidence of faulting was identified (ETTL, 2010).

5.2 Compliance with Fault Area Restrictions

A review of available geologic reports and maps has indicated that the Site is not located near any faults with displacement in the Holocene. Therefore, the Landfill Lateral Expansion complies with the requirement for not being located within 200 feet of the outermost damage zone of a fault that has had displacement in Holocene time.

6. Seismic Impact Zone

CCR Rule 40 CFR Part 257.63 requires that new CCR Landfill Lateral Expansions must not be located within a seismic impact zone unless the owner or operator demonstrates that all structural components of the CCR unit are designed to withstand the maximum horizontal acceleration in lithified earth material for the site.

6.1 Definition of Seismic Impact Zone

CCR Rule 40 CFR Part 257.53 defines a seismic impact zone as an area having a 2% or greater probability that the maximum horizontal acceleration expressed as a percentage of the earth’s gravitational pull (g) will exceed 0.10 g in 50 years.

6.2 Compliance with Seismic Impact Zone Restriction

Figure 19 presents the seismic hazard map for Texas, as published by the USGS. As shown on **Figure 19**, the Site falls within the zone having a maximum horizontal acceleration of 0.04 to 0.06 g. Therefore, the Landfill Lateral Expansion complies with the requirement for not being located in a seismic impact zone.

7. Unstable Areas

CCR Rule 40 CFR Part 257.64 requires that existing and new CCR landfills and lateral expansions must not be located within an unstable area unless the owner or operator demonstrates that the design of the unit will ensure the integrity of the structural components of the unit.

7.1 Definition of Unstable Area and local Conditions

7.1.1 CCR Rule Definition

CCR Rule 40 CFR Part 257.53 defines an unstable area as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of the CCR unit. These may include poor foundation conditions, areas susceptible to mass movements (landslides), and karst terrains.

7.1.2 Poor Foundation Soils

ETTL conducted a geotechnical investigation and foundation settlement evaluation of the Landfill foundation in 2005. The investigation included evaluation of the western portion of the Landfill where lignite mining operations previously occurred. The ETTL evaluation concluded the predicted Landfill settlement would not exceed approximately 4.3 feet and would not adversely affect the performance of the Landfill liner or leachate collection system, and the Landfill excavation, interim fill, and final cover would be stable on slopes of 3:1 or 4:1 (ETTL, 2005).

Apex Geoscience conducted a geotechnical investigation and foundation settlement evaluation of the Landfill in 2012, including advancement of two CPT borings in the western portion of the Landfill where lignite mining operations had previously occurred. The report predicted estimated settlement of 39.07 inches (3.26 feet) and concluded the Landfill would be stable with side slopes of 3:1 (Apex Geoscience, 2013).

Auckland Consulting conducted geotechnical evaluation of the 2018 Landfill Lateral Expansion area in 2016, including advancement of eight soil borings (B1 through B8) through the Lateral Expansion area, and a settlement analysis based on CCR material loading to the maximum design waste height of 120 feet. The report predicted estimated settlement of up to 43.96 inches (3.66 feet) and concluded the Lateral Expansion would be stable with side slopes of 3:1 (horizontal to vertical) and bench widths of approximately 16 feet (Auckland Consulting, 2016). The report also stated the fill soils to be emplaced below the liner system in the topographically lower central and northern portions of the Lateral Expansion will be placed in loose lifts not exceeding 8 inches and compacted to a minimum 95% of the maximum density as determined by Standard Proctor test ASTM D 698 (Auckland Consulting, 2016).

7.1.3 Mass Movements

Geotechnical evaluations of the Landfill by ETTL in 2005, Apex Geoscience in 2012, and Auckland Consulting in 2016 concluded the Landfill would not be subject to mass movements that could impair the integrity of the Landfill based on side slopes of 3:1 (ETTL, 2005; Apex Geoscience, 2013; Auckland Consulting, 2016).

7.1.4 Karst

The site area is located on the outcrop of unconsolidated Cretaceous Formations consisting predominantly of sand and clay (Broom, 1966; Flawn, 1965). The Landfill is not located in a karst area.

7.1.5 Subsurface Mining

Naturally occurring lignite is present in portions of the Site area, and a naturally occurring lignite seam was identified at an elevation of approximately 270 feet amsl at monitoring well AD-24 as shown on Geologic Cross Section D-D’ (**Figure 7**). The Texas Water Development Board Ground-Water Resources Report for Harrison County, Texas, states that the Wilcox Formation, which underlies the Carrizo Sand, contains lignite (Broom, 1966).

Lignite mining operations using a drag line had occurred in the western portion of the Landfill prior to Landfill construction in this area (VFL Technology Corporation, 1984). The drag line mining method is a surface mining method. A geotechnical evaluation of the previously mined western portion of the Landfill was conducted by ETTL in 2005. The ETTL report indicated the western portion of the Landfill had been mined in the past to a depth of 50 to 100 feet using a dragline, and the spoils (reclaimed soil) were returned to the excavation. The geotechnical evaluation included installation of 30 soil borings, ten CPT borings, and geotechnical testing of soil samples. The ETTL report concluded the Landfill would be stable based on the Landfill liner system (compacted clay or GCL overlain by HDPE or VLDPE), leachate drainage system (lateral underdrain consisting of permeable bottom ash), and Landfill side slopes no steeper than 3:1 (ETTL, 2005).

No subsurface mining is known to exist below the 2018 Landfill Lateral Expansion area.

7.2 Compliance with Unstable Areas Restriction

Based on our review of available information, including the 2005 geotechnical evaluation of the Landfill by ETTL, the 2012 geotechnical evaluation of the Landfill by Apex Geoscience, and the 2016 geotechnical evaluation of the Lateral Expansion Area by Auckland Consulting, this CCR unit complies with the requirement for not being located in an unstable area.

8. Summary, Conclusions, and PE Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, as well as the evaluations discussed within this report, the H.W. Pirkey Power Plant 2018 Landfill Lateral Expansion complies with the requirements of the location restrictions sections of 40 CFR 257 Subpart D that apply to landfills and therefore the CCR unit is not located in a restricted location.

1. Objective

This report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to assess the location of the existing Stack Out Area relative to the location restrictions included in the Coal Combustion Residual (CCR) requirements, as specified in the Code of Federal Regulations (CFR) 40 CFR 257.60 through 257.64, at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The CCR requirements include an evaluation of the adequacy of the groundwater monitoring well network to characterize groundwater quality up and down gradient of the CCR unit and an evaluation of whether the CCR unit meets up to 5 location restrictions, which include: the base of the CCR unit is 5 feet (ft) above the uppermost aquifer, the CCR unit may not be located in a wetland, within 200 ft of the damage zone of a fault that has displacement during the Holocene, within a seismic impact zones, or in an unstable area. However, because the subject CCR unit for this report (Stack Out Area) is an existing above-grade CCR pile/landfill, this CCR unit is subject to one location restriction: unstable area.

Four regulated CCR units associated with the Plant were identified for review, which include the West Bottom Ash Pond (BAP), East BAP, Stack Out Area, and Landfill (**Figure 2**). This report summarizes the evaluation of the location restriction criteria at the existing Stack Out Area (Site). The evaluation of the groundwater monitoring well network in the uppermost aquifer for the Stack Out Area is not included in this report and will be completed under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the Stack Out Area CCR unit, as well as publically-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on documents reviewed and will further describe the uppermost aquifer.

2. Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant Stack Out Area.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The Stack Out Area CCR unit is located in the central portion of the Plant, and approximately 1,200 feet northwest of Brandy Branch Reservoir (**Figures 1** and **2**).

2.2 Description of Stack Out Area CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the Stack Out Area.

2.2.1 Embankment Configuration

The Stack Out Area is an approximate 7-acre storage area for stabilized flue gas desulfurization (FGD) sludge. As shown on **Figure 3**, the Stack Out Area is located directly south of the Surge Pond, directly west of Thickener Tanks 1A and 1B, and directly east of a road that runs south to the on-site Landfill. The dimensions of the Stack Out Area are approximately 650 feet from north to south by 450 feet from east to west.

Stabilized FGD sludge is temporarily stockpiled directly above natural ground surface (native clay) in the Stack Out Area using a radial stacker. The maximum height of the stabilized FGD sludge piles are approximately 41 feet above ground surface. There are no embankments in the Stack Out Area. The stabilized FGD sludge piles are located no closer than approximately 50 feet from the perimeter of the Stack Out Area, thereby preventing the stabilized FGD sludge from migrating beyond the boundaries of the Stack Out Area.

2.2.2 Area/Volume

The Stack Out Area is approximately 7 acres in size. However, as discussed above in Section 2.2.1, the CCR piles in the Stack Out Area are located no closer than approximately 50 feet from the perimeter of the Stack Out Area, therefore the effective storage area of the Stack Out Area is approximately 4.4 acres (550 feet by 350 feet), and the maximum CCR storage volume based on a maximum CCR pile height of 41 feet is 180 acre feet.

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, FGD sludge) have been generated. The Stack Out Area receives stabilized FGD sludge (**Figure 3**). Prior to storing the FGD sludge in the Stack Out Area, the FGD sludge is dewatered using belt presses, and the dewatering fluid is routed to the Surge Pond for reuse as FGD makeup water. The stabilized FGD sludge is then stockpiled in the Stack Out Area using a radial stacker with an approximate 3-foot-wide by 120-foot-long conveyor belt.

The stabilized FGD sludge is temporarily stored at the Stack Out Area. The stabilized FGD sludge is removed using front-end loaders or similar equipment, placed into trucks, and disposed of at the on-site Landfill CCR Unit located near the south end of the Plant.

Lithologic data from soil borings and monitoring wells confirm the native soils underling the Stack Out Area consist of low-permeability clay. As shown on Geologic Cross Sections B-B' (**Figure 5**) and E-E' (**Figure 8**), the native clay directly below the Stack Out Area extends from the surface to an average depth of approximately 20 feet. Therefore, as shown on **Figures 5** and **8**, the separation distance between the base of the Stack Out Area and uppermost aquifer exceeds 5 feet.

2.2.4 Surface Water Control

The Stack Out Area contains dewatered FGD sludge that is stockpiled using a radial stacker, therefore no sluice water is present in the Stack Out Area. Storm water in the Stack Out Area follows surface topography via gravity sheet flow. The ground surface elevation in the Stack Out Area ranges from approximately 360 to 365 feet amsl (Akron Consulting, 2015). Storm water flow in the Stack Out Area is in a general northerly direction to the Surge Pond, which is a below-grade (incised) non-CCR unit.

2.3 Previous Investigations

The initial soils investigation and design of the Plant was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, including the Stack Out Area.

In 2009, ETTL Engineers & Consultants (ETTL) conducted geotechnical investigations of earthen embankments associated with several ponds at the Plant. The Stack Out

Area was not included in this evaluation because there are no earthen embankments in the Stack Out Area (ETTL, 2010).

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, 2011).

In 2011, Johnson & Pace performed hydraulic analysis of several ponds at the Plant. The Stack Out Area was not included in this evaluation because there is no impounded water in the Stack Out Area (Johnson & Pace, May 2011).

In 2015, Auckland Consulting further expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-30 through AD-35 (Auckland Consulting, 2016).

2.4 Hydrogeologic Setting

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Plant. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of approximately 100 feet (Broom, 1966).

These features are further illustrated on five lines of cross section that were prepared through the Stack Out Area, with three lines trending from west to east (A-A'; B-B'; C-C'), and the other two lines trending from north to south (D-D'; E-E'). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure 4** (A-A') through **Figure 8** (E-E').

2.4.1 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1° Fahrenheit (F) in January to 83.8°F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.2 Regional and Local Geologic Setting

The central and northern portions of the Plant, including the Stack Out Area, are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 "*Ground-Water Resources of Harrison County, Texas*" (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology "*Geologic Atlas of Texas – Tyler Sheet*" (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K "*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*" (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled "*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*" (ETTL, 2010).

2.4.3 Surface Water and Surface Water Groundwater Interactions

Figure 9 is a potentiometric surface map based on January 2016 water level data for the uppermost water bearing unit at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1**. As shown on **Figure 9**, shallow groundwater flow direction in the Stack Out Area is westerly to northwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The Stack Out Area is located approximately 1,200 feet northwest of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980's. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figure 9**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore shallow groundwater in the Stack Out Area does not discharge into Brandy Branch Reservoir. Brandy Branch Reservoir likely recharges the uppermost water bearing unit in the southern portion of the Plant, where the pool level in the Reservoir (340 feet amsl) is higher than water level elevations in monitoring wells located southwest (downslope) of the Reservoir.

2.4.4 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled approximately 1,000 feet north of the Stack Out Area in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 350 to 430 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled approximately ¼-mile west (downgradient) of the Stack Out Area for NFR Energy in 2008 for use as a rig supply well. The water well was screened from 250 to 310 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth, and is located approximately ¼-mile east (upgradient) of the Pirkey Power Plant.

3. Unstable Areas

CCR Rule 40 CFR Part 257.64 requires that existing landfills must not be located within an unstable area unless the owner or operator demonstrates that the design of the unit will ensure the integrity of the structural components of the unit. The Stack Out Area consists of stabilized FGD sludge which is stockpiled in above-ground piles, and is a CCR landfill.

3.1 Definition of Unstable Area and local Conditions

3.1.1 CCR Rule Definition

CCR Rule 40 CFR Part 257.53 defines an unstable area as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of the CCR unit. These may include poor foundation conditions, areas susceptible to mass movements (landslides), and karst terrains.

3.1.2 Poor Foundation Soils

Lithologic data from soil borings and monitoring wells show the foundation of the Stack Out Area consists of native clay from the base of the CCR unit (ground surface) to a depth ranging from approximately 10 to 20 feet below ground surface. As shown on

Geologic Cross Section B-B' (**Figure 5**) and E-E' (**Figure 8**), the uppermost clay stratum is underlain by a clayey and silty sand stratum. These native sediments provide a stable foundation for the CCR materials that are temporarily stockpiled in the Stack Out Area prior to disposal in the on-site Landfill.

3.1.3 Mass Movements

The Stack Out Area is not located within an area subject to mass movements. This conclusion is supported by the ETTL soil stability report (ETTL, 2010).

3.1.4 Karst

The site area is located on the outcrop of unconsolidated Cretaceous Formations consisting predominantly of sand and clay (Broom, 1966; Flawn, 1965). The Stack Out Area is not located in a karst area.

3.1.5 Subsurface Mining

No subsurface mines are known to exist below the CCR units at the Site.

3.2 Compliance with Unstable Areas Restriction

Based on our site visit and review of available information, the Stack Out Area is not located within unstable areas. Therefore, this CCR unit complies with the requirement for not being located in an unstable area.

4. Summary, Conclusions, and PE Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, as well as the evaluations discussed within this report, the H.W. Pirkey Power Plant Stack Out Area complies with the requirements of the location restrictions sections of 40 CFR 257 Subpart D that apply to existing landfills and therefore the CCR unit is not located in a restricted location.

TABLE OF CONTENTS

2018 LANDFILL CELL
LINER AND LEACHATE COLLECTION CONSTRUCTION CERTIFICATION

LIST OF EXHIBITS

Introduction and Purpose

The H.W. Pirkey Power Plant, operated by Southwestern Electric Power Company (SWEPCO), a unit of American Electric Power (AEP), recently completed construction of a new +/-4 acre lateral expansion of their CCR landfill, generally referred to as the 2018 Landfill Cell. As required in section 40 CFR 257.70 (f), the purpose of this report is to certify that the composite liner and the leachate collection and removal system were constructed in accordance with the requirements of § 257.70 for the 2018 Landfill Cell.

Facility Location Description

SWEPCO owns and operates a coal-fired power plant (H.W. Pirkey Power Plant), which is located approximately 5.9 miles southeast of Hallsville in Harrison County, Texas. The power plant produces up to 700 Megawatts (MW) of electrical power utilizing local lignite from the Sabine Mining Company. The existing landfill is used for disposal of scrubber sludge, fly ash, bottom ash, and other byproducts from the coal-fired power plant. The waste materials are considered non-hazardous. A Site Location Map, as well as a Plant and CCR Unit Map have been included for reference at the end of this report.

2018 Landfill Cell Design Criteria for New CCR Lateral Expansion: (§ 257.70)

The existing Pirkey Landfill consists of several cells that have been constructed periodically over the last thirty plus years. Several of the cells have already been capped, and the most recent cell was constructed in 2015 (please refer to the Site Layout Map for the capped and active area locations). As per § 257.70, all new CCR landfills and any lateral expansions must be designed, constructed, operated, and maintained with a composite liner system and a leachate collection and removal system. The details of this system have been described in more detail below and illustrated on the last page of this document, entitled 2018 Landfill Cell Details.

Composite Liner System Requirements: § 257.70 (b) (1-4)

The composite liner system for the 2018 Landfill Cell consists of an upper and lower component. The upper component consists of a 60 mil HDPE geomembrane, and the lower component consists of a 2-foot compacted clay liner system with a hydraulic conductivity of no more than 1×10^{-7} cm/sec. The upper component was installed in direct and uniform contact with the lower component. The composite liner system also meets all the requirements as outlined in § 257.70 (b) (1-4).

Leachate Collection and Removal System § 257.70 (d) (1-3)
(Not Installed for Lined Area to the South)

The leachate collection and removal system was installed for the 2018 Landfill Cell. This leachate system consists of a minimum 2-foot thick leachate drainage layer above the 60-mil HPDE liner to maintain less than a 30 cm depth of leachate over the liner. The purpose of this system is to collect and remove the leachate from the landfill during the active life and post-closure care period. The leachate system was constructed of materials that are chemically resistant to the CCR and of sufficient strength to prevent collapse from the future overlying waste. Leachate pipes, also made from HDPE material, were installed in the low areas of the liner system to remove the leachate from the leachate drainage layer. The trenches around these leachate pipes were backfilled with coarse aggregate and wrapped with filter fabric to minimize clogging. Chimney drains were also installed into the leachate piping to better drain the landfill during its active life. Therefore, the leachate collection and removal system meets all the requirements as outlined in § 257.70 (d) (1-3). This system was not installed on the lined area to the south of the 2018 Landfill Cell due to current ash projections. Consequently, this area is not included as part of this certification.

Summary

SWEPCO owns and operates a landfill at the H.W. Pirkey Power Plant and recently constructed the 2018 Landfill Cell. As outlined in this report, the liner and leachate collection and removal system were constructed in accordance with the requirements of § 257.70 for the 2018 Landfill Cell.

Certification

By means of this certification, I attest that (i) this report was prepared by me or under my direct supervision, (ii) I am a duly Licensed Professional Engineer in the State of Texas, and (iii) to the best of my knowledge, information and belief, the composite liner and the leachate collection and removal system for the 2018 Landfill Cell meets the requirements as set forth in 40 CFR 257.70.

2.4 – East Bottom Ash Pond Hazard Potential Classification Assessment, July 2021

Southwestern Electric Power Company
Pirkey Power Station
East Bottom Ash Pond

Hazard Potential Classification Assessment

AEP has performed an evaluation to classify the above CCR Surface Impoundment in accordance with FEMA's Hazard Potential Classification System for Dams. These guidelines evaluate the consequences of a potential failure not the likelihood of a failure. Guidelines that were developed and utilized are included below.

Hazard Potential Classification Systems (from FEMA 333, April 2004)

1. **Low Hazard Potential**
   Dams assigned the low hazard potential classification are those where failure or mis-operation results in no probable loss of human life and low economic and/or environmental losses. Losses are principally limited to the owner's property.
2. **Significant Hazard Potential**
   Dams assigned the significant hazard potential classification are those dams where failure or mis-operation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in areas with population and significant infrastructure.
3. **High Hazard Potential**
   Dams assigned the high hazard potential classification are those where failure or mis-operation will probably cause loss of human life.

The AEP H.W. Pirkey Power Station is located at 2400 FM 3251, Hallsville, TX 75650. The plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas.

The East Bottom Ash Pond is located at the north end of the Plant and approximately 2,000 feet north-northwest of Brandy Branch Reservoir. Loss of human life is not probable in the event of a catastrophic failure of the embankment and a failure of the embankment is expected to have a low economic and environmental impact. The US EPA CCR Impoundment Assessment Report has listed this ash pond as Low Hazard.

There has been no changes in classification by the State Dam Safety nor has there been any other physical changes that would warrant a change in the classification.

Based on the FEMA Hazard Potential Classification Systems for Dams and on the above discussion, Pirkey East Bottom Ash Pond Dam is classified as a **Low Hazard Potential Dam**.

Professional Engineer's Certification:

I certify that this Hazard Potential Classification Assessment is in accordance with the requirements of section 30 TAC 352.731.

1.0 OBJECTIVE

This report was prepared by AEP- Geotechnical Engineering Services (GES) section to fulfill requirements of CCR 257.73(c)(1) with an evaluation of the facility.

2.0 DESCRIPTION OF CCR THE IMPOUNDMENT

The Henry W. Pirkey Power Station is located at 2400 FM 3251 and south of Hallsville, Texas.
It is owned and operated by Southwest Electric Power Company (SWEPCO). The facility operates two surface impoundments for storing CCR materials called the East Bottom Ash Pond (East BAP) and the West Bottom Ash Pond (West BAP).

The East BAP is located directly adjacent to and east of the West BAP. The East BAP receives sluiced bottom ash and has a surface area of 30.9 acres and a storage capacity of 188 acre-feet. The pond is almost entirely incised, with a reported maximum embankment height of 4 feet.

The West BAP, which also receives sluiced bottom ash, is located northwest of the main plant buildings and shares its eastern border with the western border of the East BAP. The West BAP receives sluiced bottom ash and has a surface area of 30 acres and a storage capacity of 188 acre-feet. The maximum embankment height is 25 feet. Design material include in the provided documentation indicate that the main upstream embankment slopes are 3 feet horizontal to 1 foot vertical (3:1 H:V); while the main downstream slopes area 2.5:1 H:V.

3.0 SUMMARY OF OWNERSHIP 275.73(c)(1)(i)

[The name and address of the person(s) owning or operating the CCR unit: the name associated with the CCR unit: and the identification number of the CCR unit if one has been assigned by the state.]

The AEP H.W. Pirkey Power station is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The Plant Power Station Address is 2400 FM 3251, Hallsville, Texas . It is owned and operated by Southwestern Electric Power Company (SWEPCO). The facility Bottom Ash Complex operates two surface impoundments for storing CCR and a clear water pond for decant water.

4.0 LOCATION OF THE CCR UNIT 275.73 (c)(1)(ii)

[The location of the CCR unit identified on the most recent U.S. Geological Survey (USGS) 7 ½ minute or 15 minute topographic quadrangle map, or a topographic map of equivalent scale if a USGS map is not available.]

A location map is included in Attachment A.

5.0 STATEMENT OF PURPOSE 275.73 (c)(1)(iii)

[A statement of the purpose for which the CCR unit is being used.]

The Bottom Ash Pond Complex is a surface impoundment for storing CCR. The Bottom Ash Ponds within the complex are used for primary settling and storage of bottom ash. The decant water from the Bottom Ash ponds flow s into a secondary pond that provides storage of decant water.

6.0 NAME AND SIZE OF WATERSHED THE CCR UNIT IS LOCATED 275.73 (c)(1)(iv)

[The name and size in acres of the watershed within which the CCR unit is located.]

The Pirkey East BAP and West BAP are comprised of diked embankments on all sides which direct stormwater away from the impoundment and limit runoff to that which falls directly on the water surface. Therefore, the areas surrounding the impoundments do not contribute any runoff. The watershed for the ponds is equal to the surface areas of the ponds and is approximately 61 acres.

The bottom ash ponds are located within the Region 12 - Texas Gulf Region Watershed and are part of the sub group HUC = 12010002 Middle Sabine watershed area. The area is approximately 1770009.6 acres.

7.0 DESCRIPTION OF THE FOUNDATION AND ABUTMENT MATERIALS 275.73(c)(1)(v)

[A description of the physical and engineering properties of the foundation and abutment materials on which the CCR unit is located.]

The foundaion materials for the East BAP are native soils which consist of stiff to very stiff sandy lean clay (CL) and sandy fat clay (CH) with intermittent layers of medium dense to dense silty sand (SM) and clayey sand (SC). Atterburg Plasticity Indices of tested soils ranged between a low of 16 to a high of 39.

The foundation materials for the West BAP are native soils which consist primarily of medium dense to very dense clayey sand (SC) with layers of of dense clayey gravel (GC) and very dense silty clayey sand (SC-SM). Atterburg Plasticity Indices of tested soils ranged between a low of 9 to a high of 46. The engineering properties of the foundation soils had a cohesion that ranged between 290 psf and 430 psf and a friction angle that ranged between 17 degrees and 28 degrees. Additioanl details on the engineering properties of the foundaiton soils is in the design reports presented in Attachment B.

8.0 DESCRIPTION OF EACH CONSTRUCTED ZONE OR STAGE OF THE CCR UNIT 275.73 (c)(1)(vi)

[A statement of the type, size, range, and physical and engineering properties of the materials used in constructing each zone or stage of the CCR unit; and the approximate dates of construction of each successive stage of construction of the CCR unit.]

The East BAP is primarily incised into native soils with an embankment height of approximately 4 feet (AMEC, 20110). The East BAP embankments are constructed of compacted clay on a 3:1 slope (3 feet horizontal, 1 foot vertical) (Sargent & Lundy, 1983). The embankment soils are stiff to very stiff sandy lean clay (CL) and sandy fat clay (CH) with intermittent layers of medium dense to dense silty sand (SM) and clayey sand (SC). The elevation of the top of embankment around the perimeter of the East BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, May 2011). The interior bottom elevation of the East BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Johnson & Pace, June 2011. A copy of the referenced design documents and design drawings are presented in attachment B & C.

The West BAP embankments have maximum height of approximately 25 feet and are constructed of compacted clay on a slope ranging from 2.5:1 (2.5 feet horizontal, 1 foot vertical) to 3:1 (Sargent & Lundy). The elevation at the top of the embankment around the perimeter of the West BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, 2011). The embankment fill materials are stiff to very stiff lean clay (CL) and/or fat clay (CH), overlying native soils consisting of dense to very dense clayey sand (SC) with intermittent layers of dense gravel (GC) and very dense silty clayey sand (SC-SM). The interior bottom elevation of the West BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Akron Consulting, 2012). The engineering properties of embankment soils had a cohesion of 590 psf and a friction angle of 16 degrees. Additioanl details on the engineering properties of the foundaiton soils is in the design reports presented in Attachment B.

A copy of the referenced design documents and design drawings are presented in attachment B & C.

9.0 ENGINEERING STRUCTURES AND APPURTENANCES, 275.73 (c)(1)(vii)

[At a scale that details engineering structures and appurtenances relevant to the design, construction, operation, and maintenance of the CCR unit, detailed dimensional drawings of the CCR unit, including a plan view and cross sections of the length and width of the CCR unit, showing all zones, foundation improvements, drainage provisions, spillways, diversion ditches, outlets, instrument locations, and slope protection…]

The bottom ash from the plant is sluiced to the Ash Ponds using sluice pumps that convey the ash slurry through a pipeline which discharges the slurry into the middle of the pond. The slurry is sluiced at the rate of 3,000 gallons per minute (GPM) per pump. During normal operations only one pump is used at a time. The bottom ash settles, and the decant water is discharged from the Ash Ponds using either a portable pump or by overflowing into the Secondary Pond through a vertical box weir structure that contains a 36-inch diameter corrugated metal pipe (CMP) and manually operated gate valve. Additional discharge outlets convey relatively minor quantities into the ponds, including the boiler blowdown outlet which conveys about 35 GPM to the Secondary Pond. None of the ponds have a designated emergency spillway. The decant water from the Secondary Pond is re-used by pumping it out of the pond using the ash recirculation pumps (housed in a pump 4 house structure). Of the four recirculation pumps, only three are normally operated and convey average flows of about 2,000 GPM each. Flow to and from the ponds is balanced by conveying the water from the recirculation pumps to a suction tank that is used by the sluice pumps to remove the ash from the boiler and then return it to the Ash Ponds. A permitted outfall valve is located near the southwest corner of the Secondary Pond and discharges into a runoff ditch on the south side of the pond that eventually conveys water to Hatley Creek. The gate valve is typically closed.

For location and details of all appurtenances see design drawings presented in Attachment C and for a map of the instrumentation locations see Attachment D.

10.0 SUMMARY OF POOL SURFACE ELEVATIONS, AND MAXIMUM DEPTH OF CCR, 275.73 (c)(1)(vii)

[…in addition to the normal operating pool surface elevation and the maximum pool elevation following peak discharge from the inflow design flood, the expected maximum depth of CCR within the CCR surface impoundment.]

The table below describes the normal pool elevations and maximum pool elevations as well as maximum depth of CCR within the impoundment. The Inflow Design Flood is the 100-year storm event.

	West Bottom Ash Pond	East Bottom Ash Pond
Normal Pool Elevation	354.0	354.0
Maximum Pool Elevation following peak discharge from inflow design flood	355.01	354.99
Expected Maximum depth of CCR within impoundment	7.5 ft	7.5 ft

11.0 FEATURES THAT COULD ADVERSELY AFFECT OPERATION DUE TO MALFUNCTION OR MIS-OPERATION (275.73 (c)(1)(vii))

[…and any identifiable natural or manmade features that could adversely affect operations of the CCR unit due to malfunction or mis-operation]

In the event of malfunction or mis-operation of any of the pond’s appurtenances the ponds operations could be adversely affected. These structures include weir structures and piping between pond cells, low water discharge gated structures, gated weir structures, effluent return piping and pump structures and influent sluicing piping and structures. See design drawings in Attachment C for location and details of all appurtenances.

<u>12.0</u> DESCRIPTION OF THE TYPE, PURPOSE AND LOCATION OF EXISTING INSTRUMENTATION 275.73 (c)(1)(viii)

[A description of the type, purpose, and location of existing instrumentation.]

The East BAP has no instrumentation.

The West BAP has 2 piezometers located within the structure of the dam. These piezometers are read every 30 days for the purpose of determining the phreatic water level within the dike. A location map is provided in Attachment D.

<u>13.0</u> AREA – CAPACITY CURVES FOR THE CCR UNIT 275.73 (c)(1)(ix)

[Area-capacity curves for the CCR unit.]

The area capacity curves for the Bottom Ash Pond Complex are included in the Hydrology and Hydraulic Analysis Report by Aukland, 2015 in Attachment E.

<u>14.0</u> 275.73 (c)(1)(x) DESCRIPTION OF EACH SPILLWAY AND DIVERSION

[A description of each spillway and diversion design features and capacities and calculations used in their determination.]

Complete details of each spillway structure are included with the design drawings in Attachment C. Hydrology and Hydraulic Analysis which include calculations for each spillway structure are included in Attachment E.

The surface water elevation in the East BAP is controlled by a weir box and a manually operated gate valve on a 36-inch diameter discharge pipe at the southwest corner of the pond. Clear water overflow from the East BAP discharges through the 36-inch diameter pipe into a 2.7 acre Clearwater Pond located directly south of the East BAP. Water in the Clearwater Pond is either pumped (re-circulated) back into the boiler ash hopper, or gravity discharged through a pipe at the southwest corner of the Clearwater Pond into an unnamed intermittent tributary of Hatley Creek via outfall 006 in accordance with Texas Pollutant discharge Elimination system (TPDES) Permit no. WQ0002496000.

The surface water elevation in the West BAP is controlled by a weir box and a manually operated gate valve on a 36-inch-diameter discharge pipe at the southeast corner of the pond. Clear water overflow from the West BAP discharges through the 36-inch diameter pipe into a 2.7 acre Clearwater Pond located southeast of the West BAP. Water in the Clearwater Pond is either pumped (re-circulated) back into the boiler ash hopper, or gravity discharged through a pipe at the southwest corner of the Clearwater Pond into an unnamed intermittent tributary of Hatley Creek via outfall 006 in accordance with Texas Pollutant discharge Elimination system (TPDES) Permit no. WQ0002496000.

<u>15.0</u> SUMMARY CONSTRUCTION SPECIFICATIONS AND PROVISIONS FOR SURVEILLANCE, MAINTENANCE AND REPAIR 275.73 (c)(1)(xi)

[The construction specifications and provisions for surveillance, maintenance, and repair of the CCR unit.]

Readily available portions of the original construction specifications are included in Appendix B.

As required by the CCR rules the East and West Bottom Ash Ponds are inspected at least every 7 days by a qualified person. Instrumentation data is collected at least every 30 days and reviewed by AEP Engineering Services. Also as a requirement of the CCR rules the impoundment is also inspected annual by a professional engineer.

If repairs are found to be necessary during any inspection they will be completed as needed.

16.0 RECORD OR KNOWLEDGE OF STRUCTURAL INSTABILITY 275.73 (c)(1)(xii)

[Any record or knowledge of the structural instability of the CCR unit.]

To date there has been no known record of knowledge of the structural instability of the CCR unit.

LIST OF EXHIBITS

HENRY W. PIRKEY POWER PLANT
DESIGN SUMMARY FOR LIGNITE STORAGE AREA AND WASTEWATER POND FACILITIES

SOUTHWESTERN ELECTRIC POWER COMPANY

I INTRODUCTION

This report is prepared by Sargent & Lundy (S&L) at Southwestern Electric Power Company's (SWEPCO) request to summarize the design of the lignite storage area and the wastewater pond facilities with regard to technical guidelines and requirements of the Texas Department of Water Resources (TDWR). The technical guidelines referenced in this report are Technical Guide Nos. 4 and 6 titled Ponds and Lagoons, and Monitoring/Leachate Collection Systems respectively. Guide No. 4 was revised March 1, 1978 and Guide No. 6 March 21, 1980. We understand that the TDWR has the responsibility of preparing and issuing document approval for disposal of wastes. Requirements concerning waste storage and disposal and concerning the design, construction, and monitoring of wastewater pond facilities are discussed in this report.

The wastewater pond facilities discussed in this report and shown in Exhibit 1 are the lignite pile runoff basin, surge pond, two bottom ash storage basins, secondary settling pond, and the metal cleaning waste pond. Discussion of other waste treatment facilities such as the sanitary sewage treatment plant, the cooling pond, and the final treated Flue Gas Desulfurization (FGD) sludge disposal site are not within the scope of this report and, therefore, not included.

II SUMMARY AND CONCLUSIONS

Based on the evaluation of the site subsurface soil and water conditions, it is concluded that the design of the Henry W. Pirkey wastewater ponds conforms with the technical guidelines and requirements of the TDWR.

Nine groundwater monitoring wells will be located adjacent to the wastewater ponds. These wells will be designed and installed to requirements equal to or exceeding those suggested by the TDWR.

A summary of design guidelines and requirements suggested by the TDWR and those used for design of the Henry W. Pirkey wastewater ponds is given in Exhibit 2.

III DESIGN OF LIGNITE STORAGE AREA AND WASTEWATER POND FACILITIES

A. General

The general site layout is shown in Exhibit 1. The plant water usage and waste water scheme is shown on Exhibit 3. The lignite storage area, lignite pile runoff basin, metal cleaning waste pond, and surge pond have been sized to accommodate two units. Each bottom ash basin will accommodate storage of hydraulically placed ash for two units for 6 months. When one bottom ash basin is filled, storage will begin in the second basin while the first basin is being emptied and readied for reuse. The in-service bottom ash basin will also receive the discharge from the ash hopper pit sump pumps.

Effluent from the bottom ash basins will discharge to the secondary settling pond. Blowdown from the main and auxiliary boilers will also be routed to the secondary pond. Water collected in the secondary settling pond will be recirculated back to the plant to transport bottom ash. Excess water is pumped to the waste water treatment plant for treatment prior to release.

Drainage from the lignite and limestone storage areas and handling systems will be collected via ditches and routed to the lignite pile runoff basin. The contents of the lignite pile runoff basin will normally not require more treatment than sedimentation. Once the suspended solids are within acceptable limits, the basin contents will be discharged to the cooling pond by means of a sluice gate. If treatment other than gravity settling is required, the contents of the lignite pile runoff basin will be pumped to the wastewater treatment plant prior to release.

The surge pond is divided into two sections: the main surge pond and an auxiliary surge pond. The auxiliary surge pond is a collection and settling pond for scrubber waste slurry, either from the FGD system waste slurry pumps, thickener underflow pumps, or filtrate overflow sump pumps. These slurry flows will be routed to the auxiliary surge pond only under emergency conditions and allowed to thicken by gravity settling. The sludge formed when the slurry thickens will be removed by front end loader and conveyed to the sludge treatment system for stabilization. The water decanted from the thickened slurry, and not evaporated, will drain to the surge pond. In emergencies, the auxiliary surge pond overflows to the surge pond.

The main surge pond is a collection basin for various FGD waste streams. Drains, overflows, backwash, blowdown, and surface drainage from the FGD system will drain to the surge pond. The reclaim water sump will overflow to the surge pond.

Rainwater runoff from the sludge truck load out area, from under the sludge conveyors, and from the sludge reclaim area will drain to the surge pond by gravity. The water decanted from the auxiliary surge pond will drain to the surge pond. The collected water in the surge pond will be pumped to the thickeners for removal of sediment and used as make-up for the SO_2 scrubbers. Drainage entering the surge pond will not leave the plant except as makeup to the scrubbers, as water hydrated with the stabilized FGD sludge, or through evaporation.

Waste from air heater wash, precipitator wash and boiler chemical cleaning is discharged to the metal cleaning pond for storage. This pond is designed to accommodate all the wastewater containing heavy metals generated in 24 hours by cleaning all the three air heaters associated with one unit. Water collected in the metal cleaning waste pond will be pumped to the waste water treatment system for processing before being discharged to the cooling pond.

B. Lignite Storage Area and Runoff Basin Design

The location and layout of the lignite storage area and lignite pile runoff basin are shown on Exhibit 1. Five borings have been drilled in this area and their locations are shown on Exhibits 4 and 5. Copies of the boring logs are included in Appendix A. Based on the results of the boring data, the lignite storage area and lignite pile runoff basin are located over surface soil deposits of dense silty sand and sandy silt (SM and ML Unified Soil Classification). A summary of the laboratory test results on samples from these borings is given in Exhibit 6. All soil borings and soil laboratory test results given in this report, with the exception of Boring B14, have been drilled and tested by NFS/National Soil Services, Inc., Dallas, Texas. Boring B14 was drilled and tested by East Texas Testing Laboratory, Inc., Tyler, Texas. Complete laboratory index property and permeability test results for all samples from borings located in or near wastewater pond facilities are included in Exhibit 6. Also included for reference are index property and permeability values for various types of soils from other onsite borings.

The lignite pile runoff basin is an above and below ground pond designed to store lignite pile and limestone pile runoff. Plan and cross sections are shown in Exhibit 5. The lignite storage pile will be underlain by two feet of compacted cohesive fill (SC, CL, and CH Unified Soil Classification). The drainage ditches transporting runoff from the storage area to the basin will be lined with minimum 18 inches of compacted cohesive fill. The runoff basin will be lined on the bottom and side slopes with a minimum three feet of compacted cohesive fill. The dike fill, including lining, will be compacted as specified to a minimum 95 percent maximum density in accordance with ASTM D698. These requirements are in accordance with the guidelines suggested by the TDWR for wastewater ponds.

A summary of the parameters used for the lignite pile runoff basin design in comparison to those parameters and guidelines suggested by the TDWR is given in Exhibit 2. The runoff basin design parameters equal or exceed the minimum recommended values except for depth to the water table. Average or median parameter values are given where several individual tests or measurements were made. The only suggested parameter not obtainable is the TDWR recommendation that the bottom of the basin be 10 feet above the water table. The water table varies throughout the site, and with normal pool of the cooling pond at elevation 340.0 ft., it is possible that the static water table may be located within 3 feet of the bottom of the clay lining of any of the plant's wastewater ponds. Despite this, the presence of relatively homogeneous impermeable in situ and compacted clay layers should provide sufficient lining and protection of the groundwater.

Compacted clay linings are required on the bottom and side slopes of the lignite pile runoff basin and beneath the lignite storage pile. Project specifications require these compacted linings to be cohesive soils with minimum 40% passing the no. 200 sieve and having a minimum plasticity index of 15. The linings are to be compacted to minimum 95% maximum density in accordance with ASTM D698. The permeability of the compacted linings is estimated to be less permeable than or equal to 1.0×10^{-7} cm/sec. This will be verified by SWEPCO by testing field samples in the laboratory during or after construction.

C. Surge Pond Design

The location and layout of the surge pond are shown on Exhibit 1. Four borings have been drilled in this area and their locations are shown on Exhibits 4 and 7. Copies of the boring logs are included in Appendix A. Based on the results of the boring data, the surge pond is located within or above a thick surface deposit of silty and sandy clay (CL and CH Unified Soil Classification). The thickness of the in situ clay soils below the bottom of the pond (approximately elevation 350 ft) ranges from two and one half to 16 feet. A summary of the laboratory test results on samples from the surge pond borings is given in Exhibit 6.

The surge pond (including auxiliary surge pond) is an above and below ground pond. Dikes and excavated slopes are designed with three horizontal to one vertical side slopes. Dike fill will be cohesive soil compacted to a minimum 95 percent maximum density in accordance with ASTM D698. Typical surge pond cross sections are shown on Exhibit 7.

In situ cohesive soils will be used to function as the pond lining. Verification of the quality and thickness of the in situ lining will be made during or after construction by SWEPCO. As previously stated, the borings indicate that the thickness of the in situ lining ranges from approximately two and one half to 16 feet. Any compacted cohesive linings required will meet the density, index property, and permeability requirements as given for the lignite runoff basin.

Exhibit 2 summarizes the TDWR suggested parameters and guidelines and those parameters used for the surge pond design. Comparison of the design parameters obtained and those suggested indicate that in almost every case the obtained parameters equaled or exceeded the suggested value. The only suggested parameter not obtainable is the recommended 10 ft. depth to the groundwater table. It is possible that the groundwater table could eventually be located within 3 ft. of the bottom of the clay lining of the pond, as previously discussed.

Six laboratory permeability tests were performed on samples of undisturbed clay soil from the surge pond area. Results are given in Exhibit 8 and indicate a median permeability value of 5.1×10^{-8} cm/sec. The permeability test values ranged from 2.1×10^{-6} cm/sec. to 7.4×10^{-9} cm/sec.

D. Bottom Ash Basin and Secondary Pond Design

The location and layout of the bottom ash basins and secondary pond are shown on Exhibit 1. Plan and cross sections are shown in Exhibit 9. Nine borings have been drilled in this area. Their locations are given in Exhibits 4 and 9. Copies of the boring logs are included in Appendix A. Based on the results of the boring data, the secondary pond, bottom ash basin no. 1 and the east half of bottom ash basin no. 2 are located within or above a thick surface deposit of silty and sandy clay. These soils are classified as SC, CL, and CH material. A summary of the laboratory test results on samples from those borings is given in Exhibit 6. Results of approximately 23 tests on cohesive soils representing in situ lining indicate average fines content and plasticity index values of 78% and 36, respectively. These values significantly exceed the minimum values suggested by the TDWR.

Bottom ash basin no. 1 is an above and below ground pond located entirely in a cohesive soil deposit. The thickness of the cohesive soil below the bottom of the pond is greater than 5 feet. The plan and cross sections are given in Exhibit 9. A compacted clay lining is shown and will be used where required. In situ lining of acceptable quality and thickness exist in most of the area. This will be verified in the field during construction by SWEPCO. Shallow borings, test pits, and laboratory testing will be performed as necessary.

Bottom ash basin no. 2 is also an above and below ground pond.

A portion of this pond (west half) will require a minimum three feet thick compacted clay lining. The location where an acceptable in situ lining does not exist and where the compacted lining begins will be determined and verified in the field by SWEPCO.

The secondary pond has a bottom elevation of 344 feet. This is three feet or more below the lowest point in either bottom ash basin. During borrow excavation and construction of the embankment, the existing clay may be completely removed from areas within the pond. Where this occurs, a three foot thick compacted clay lining will be installed to the requirements of project specifications and the technical guidelines suggested by the TDWR. This will be verified in the field by SWEPCO.

Exhibit 2 summarizes the TDWR parameters and guidelines and those parameters used for the design of the bottom ash basins and the secondary pond. As indicated in Exhibit 2, the design parameters meet or exceed nearly all of the suggested values. The only suggested parameter not obtainable is the recommended depth to the groundwater table as previously discussed. The median permeability from ten laboratory tests on samples of in situ cohesive soils (generally CH classification) is approximately $7.5x10^{-9}$ cm/sec. The permeability of clay soils used for compacted cohesive linings (SC, CL, and CH classification) is estimated to be less than or equal to $1.0x10^{-7}$ cm/sec. The permeability of the compacted lining will be verified by

SWEPCO by testing field samples in the laboratory during and after construction.

E. Metal Cleaning Waste Pond

The location and layout of the metal cleaning waste pond are shown on Exhibit 1 and 10. The pond lies between the surge pond and the bottom ash basins. Borings located near the metal cleaning waste pond are shown in Exhibit 4. Review of the boring data indicates that the pond is located within or above a thick surface deposit of silty and sandy clay. Evaluation of the boring data is similar to that of the bottom ash basins.

The metal cleaning waste basin is an above and below ground pond. Plan and cross sections are given in Exhibit 10. The pond will require a minimum three feet thick clay lining where sufficient in situ clay does not exist at the design elevation. SWEPCO will verify the quality and acceptability of the lining, whether in situ or compacted.

IV GROUNDWATER MONITORING PROGRAM

Nine groundwater monitoring wells are to be installed at locations adjacent to the wastewater pond facilities. The wells will be installed after completion of pond construction. The approximate locations of these wells are given in Exhibit 12.

Four-inch diameter monitoring wells will be used because they permit use of a portable submersible pump for obtaining samples for water quality analysis. Each slotted screen for each well will be located in the most permeable soils occurring below the water table. A soil boring will be drilled at each well location to accurately define the soil strata adjacent to the well and to finalize the location and design of the well. The soils are very dense and range from a medium fine sand and silty sand to clayey sand and silty clay. The length of the screens have not yet been determined but are expected to range from 15 to 25 feet.

Technical Guide No. 6, published by the TDWR, presents guidelines for design and installation of monitoring wells. The H. W. Pirkey monitoring wells will equal or exceed these guidelines.

The groundwater monitoring program will consist of measuring and recording groundwater levels and obtaining samples for water quality analysis. The frequency for measuring levels and obtaining samples has not yet been determined. Measurements and samples will be obtained by SWEPCO and should begin at least two years before the power plant begins operation. This will allow for sufficient background data against which to compare all subsequent measurements and analyses of samples taken at the site.

SUMMARY OF PARAMETERS SUGGESTED AS GUIDELINES AND PARAMETERS OBTAINED FOR DESIGN OF HENRY W. PIRKEY WASTEWATER PONDS

Parameter (1)	Suggested Guideline (1)	Parameter Values Used for Design of Pirkey Wastewater Ponds		
		Lignite Runoff Basin	Surge Pond	Bottom Ash Basins, Secondary Settling Pond and Metal Cleaning Waste Pond
Above Ground Dikes & Berms Fill Compaction Fill Classification (5) Fill Permeability Dike or Excavation Slopes	$C_r \geq 95\%$ Standard Proctor CL, CH, and SC $K \leq 1\times10^{-7}$ cm/sec 3H to 1V	Specified $C_r \geq 95\%$ CL, CH, and SC $Km \leq 1.0\times10^{-7}$ cm/sec(2) 3H to 1V	Specified $C_r \geq 95\%$ CL & CH $Km \leq 1.0\times10^{-7}$ cm/sec(2) 3H to 1V	Specified $C_r \geq 95\%$ CL & CH (lined Slope) $Km \leq 1.0\times10^{-7}$ cm/sec(2) 3H to 1V
Pond Compacted or Insitu Cohesive Lining Thickness Permeability, K	3 ft. $K \leq 1\times10^{-7}$ cm/sec	$\geq$ 3 ft. (compacted) $Km \leq 1.0\times10^{-7}$ cm/sec(2)	5 to 17 ft. (insitu) $Km \cong 5.1\times10^{-8}$ cm/sec(3)	3 to 17 ft. (insitu & compacted) $Km \leq 1.0\times10^{-7}$ cm/sec $Km \cong 7.5\times10^{-9}$ cm/sec (insitu)(4)
Liquid Limit, LL Plasticity Index, PI Fines Content, FC Classification	$LL \geq 30\%$ $PI \geq 15$ $FC \geq 30\%$ CL, CH, OH, and SC	$LL > 30\%$ $PI > 15$ $FC \geq 40\%$ CL, CH, & SC	average LL = 54% average PI = 36 specified $FC \geq 40\%$ CL & CH	average LL = 78% average PI = 36 average FC = 78% CL & CH
Below Ground Pond Permeability, K Liquid Limit, LL Plasticity Index, PI Fines Content, FC Classification	$K \leq 1\times10^{-7}$ cm/sec $LL \geq 30\%$ $PI \geq 15$ $FC \geq 30\%$ CL, CH, OH, and SC	Below ground area of pond will be lined with 3 ft. of compacted cohesive material CL & CH material	Values given above are representative of insitu cohesive soils	Values given above are representative of insitu cohesive soils. Compacted lining 3 ft. in thickness will be placed where required
Groundwater Monitoring Well Depth to Water Table Below Pond	Yes, Required 10 ft. Recommended	Two 4 in. Diameter Gravel Pack Wells Approximately 3 ft., See Report Text	Two 4 in. Diameter Gravel Pack Wells Approximately 3 ft., See Report Text	Two and Five 4 in. Diameter Gravel Pack Wells for Metal Cleaning Waste Pond and Bottom Ash Basins, respectively. Approximately 3 ft., See Report Text

NOTES:

(1) Parameters and Guidelines given are suggestions stated in the Texas Department of Water Resources Technical Guides No. 4 revised March 1, 1978, and No. 6 revised March 21, 1980.

(2) Estimated. To be verified by SWEPCo during or after construction.

(3) Median permeability from six tests on undisturbed cohesive soil samples.

(4) Median permeability from ten tests on undisturbed soil cohesive soil samples.

(5) Classification symbols used in this Exhibit are in accordance with the Unified Soil Classification System and ASTM D2487.

(6) Standard Proctor Test performed in accordance with ASTM D698.

NOTES:

(1) Laboratory testing performed by NFS/National Soil Services, Inc., Dallas Texas for OW and P-Series Borings. Laboratory testing performed by East Texas Testing Laboratory, Inc., Tyler, Texas for B-Series Borings.

(2) Laboratory Particle Size Analysis Tests performed in accordance with ASTM D422 and D1140.

(3) Laboratory Atterberg Limit Tests performed in accordance with ASTM D423 and ASTM D422.

(4) Moisture Content of Soils performed in accordance with ASTM D2216.

COHESIVE LINING CONSTRUCTION VERIFICATION PROGRAM FOR LIGNITE STORAGE AREA AND WASTEWATER POND FACILITIES

I. INTRODUCTION

Southwestern Electric Power Company (SWEPCo) has committed to providing verification that their insitu and compacted cohesive linings for the lignite storage area and wastewater pond facilities have been constructed in accordance with project specifications and guidelines suggested by the Texas Department of Water Resources (TDWR). The wastewater pond facilities requiring verification are the lignite pile runoff basin, surge pond, two bottom ash storage basins, secondary settling pond, and the metal cleaning waste pond. Also requiring verification is the compacted cohesive lining placed beneath the lignite storage pile and for ditches transporting runoff from the pile to the runoff basin.

A summary of the design of the lignite storage area and wastewater pond facilities with respect to the guidelines suggested by the TDWR was presented in a report for SWEPCo dated January 31, 1983. In this report, which may have been submitted to the TDWR, SWEPCo has committed to the verification. This report should be reviewed concerning the applicable guidelines suggested by the TDWR and the lining and dike requirements specified. The wastewater pond facilities and lignite storage area earthwork construction is included in the scope of project specification H-4533.

II. SCOPE

The cohesive lining construction verification program will include the following for each of the wastewater pond facilities and lignite storage area.

a. A listing of all the field density tests performed on cohesive lining material during construction. A statistical summary of field dry density, field water content, and percent compaction.

b. Results of any laboratory testing performed on samples representing cohesive lining material during construction.

c. Results of laboratory testing on^continuous undisturbed samples obtained from the in-place (compacted or insitu) cohesive lining after construction. The laboratory testing will consist of sample classification, grain size, atterberg limit, and falling or con^s tant head permeability tests. If construction of the lining has not been completed at the time this program begins, as is the case with the Metal Cleaning Waste Pond, samples should be obtained during construction.

Results of the laboratory testing and field density test summary will be compared to project specifications and TDWR guidelines to document compliance. Details of the laboratory test program are given in Section III of this report.

III. LABORATORY TEST PROGRAM FOR COHESIVE LINING SAMPLES

Twenty-two undisturbed shelby tube samples shall be obtained from the cohesive lining of the six wastewater ponds and lignite storage area. The thin-walled shelby tube samples shall be in accordance with ASTM D1587. The tube shall be 3 inches outside diameter and having a length such that a minimum 24-inch sample can be obtained. Tubes may be field extruded, unless otherwise directed by the purchaser. If extruded, the entire sample shall be placed in approved containers, properly labeled and transported to the laboratory. A field log shall be prepared for all extruded samples.

Dwg. HP-56 shows the approximate location of all test samples. These locations will be staked and surveyed by the purchaser prior to beginning field work. Any pond containing water will have to be pumped dry. Most samples are located within the bottom lining of the pond or area. Some samples are located in the lining of the dike slope. Drilling or other suitable equipment shall be used to obtain the samples.

The testing contractor shall inspect the site prior to beginning the sampling, but after the locations are staked to ensure that the proper equipment is brought to the site.

After sampling each or a group of locations, each borehole shall be filled with CH clay obtained on site and compacted in 6-inch layers with suitable heavy hand tampers. Testing contractor shall make with purchaser all necessary arrangements to assure that all holes are properly filled and compacted to prevent any future pond leakage due to sampling.

The required laboratory testing is given in Table 1. All samples shall be properly classified and test results reported as required in standards.

Ground Water Monitoring Program for Lignite Storage Area and Wastewater Pond Facilities

I. INTRODUCTION

The Lignite Storage Area and Wastewater Pond Facilities at the H. W. Pirkey Station are situated generally west of the main plant area. The original topography ranges in elevation from 325 feet to 375 feet, mean sea level. The ponds are underlain by a series of stiff clay strata and dense silty sand strata. Pond and basin linings consist of in-situ cohesive soils, where available, or compacted cohesive fill where the in-situ lining thickness is less than 3 feet.

Groundwater occurs under water table conditions between elevations varying from 320 ft. in the low lying areas to 350 feet in the higher elevations. Recharge of the water table is primarily from infiltration of precipitation. Groundwater discharge is to Brandy Branch Creek, which drains the site south and east of the lignite storage area, and to Hatleys Creek, which drains the area north and west of the lignite storage area. Brandy Branch Creek will be dammed to provide a cooling pond.

The proposed ground water monitoring program consists of two phases:

1) A pre-operational phase during which baseline data are established and interpreted.

2) An operational phase during which ground water levels and ground water quality are monitored in order to identify the impact of the various ponds and drainage basins.

The proposed ground water monitoring program includes periodic measurement of groundwater levels and groundwater quality in monitoring wells installed specifically for these purposes within the area. Additional data collected for the groundwater monitoring program should include daily cooling pond level and precipitation measurements.

II. OBJECTIVES

The objectives of the proposed groundwater monitoring program are:

1) Identification of the potentiometric surface, general direction of groundwater movement, and hydraulic gradient for the aquifer(s), including seasonal fluctuations, in the vicinity of the ponds;

2) Establishment of baseline groundwater quality data prior to operation of the plant;

3) Monitoring of changes in groundwater levels that may result from infiltration from the various ponds and drainage basins;

4) Monitoring of groundwater quality during plant operation;

5) Early detection and determination of the level of contamination and general direction of movement away from the source.

III. PHYSICAL ARRANGEMENT

Single-level groundwater monitoring wells are proposed at ten locations. The locations of these monitoring wells are indicated on Dwg. HP-56. Construction details for the single-level monitoring wells are shown on Exhibit 2.

The single-level monitoring wells are screened in the upper portions of the water table or confined aquifers where the concentration of contaminants should be highest. In addition, the concentration of contaminants should decrease through the saturated thickness of the aquifer as a result of hydrodynamic dispersion.

The well locations have been chosen so that one well is located hydraulically upgradient from the active portion of the facilities and at least one monitoring well is installed hydraulically downgradient of the active area. The upgradient well will yield samples representative of the background quality of the groundwater which flows under the facility. The downgradient well is located as close as possible to the facility where it will provide the greatest opportunity for interception of migrating leachate and provide an early warning of groundwater contamination..

The proposed single-level monitoring well, shown on Exhibit 2, is a 10-inch by 4-inch, sand-pack installation. The 4-inch diameter CPVC casing is preferable to a 2-inch diameter casing because the larger diameter will facilitate collecting groundwater samples using a portable submersible pump rather than by bailing of the well. The upper portion of the annular space will be backfilled with an impermeable material to prevent surface water from entering the well bore.

IV. INSTALLATION OF GROUNDWATER MONITORING WELLS

A. Contractor shall drill a 10-inch minimum diameter borehole as indicated on the attached exhibits. The borehole shall be fully cased during drilling with a temporary 10-inch minimum diameter steel casing. Larger diameter borehole and casing may be used only if approved in advance by the Consulting Engineers and the Purchaser. The use of bentonite drilling mud to hold the borehole open will not be permitted. Once the designated depth has been reached, Contractor shall flush the casing with clear water until clear water returns to the surface. The use of biodegradable drilling mud (revert) in lieu of a fully cased borehole to hold the hole open will be permitted if Contractor can show to the satisfaction of the Purchaser and the Consulting Engineers that he can satisfactorily install and disinfect the monitoring well.

B. Contractor shall collect representative split-spoon soil samples at five foot intervals and at changes in strata during drilling. Contractor shall prepare a boring log showing the stratigraphy and groundwater level during drilling.

C. Option: Contractor may drill an initial borehole of diameter less than 10-inches to collect samples and then ream to a large diameter for the installation of the well screen, casing, and sand pack.

D. Once the soil stratigraphy and groundwater level have been determined, Purchaser's representative shall confirm the intended installation details for the groundwater monitoring well as indicated in Exhibit 2. These details shall include stratigraphy, total depth, screened interval, length and depth of granular backfill, thickness and depth of the bentonite seal, and length of grout seal. Purchaser shall approve the installation details prior to the installation.

E. Contractor shall construct the groundwater monitoring well from 4-inch diameter CPVC 4120, Schedule 40 casing as specified in ASTM F441 attached to a 20-foot length of 4-inch diameter PVC well screen with a bottom cap. Solvent cement and pipe cleaner for joining sections of CPVC pipe, fittings, and the PVC well screen shall be a type specifically intended for its use. The slot size of the well screen shall be 0.010 inch. A 9-inch diameter perforated PVC disk or equivalent device shall be attached to the bottom of the well point to permit centering of the well point in the borehole.

F. Upon placement of the CPVC casing and well screen in the borehole, Contractor shall fill the annular space between the CPVC casing-well screen assembly and 10-inch temporary casing with clean concrete sand (graded per ASTM C-33) to 5 feet above the top of the PVC well screen. The backfill material may be allowed to settle through the water in the steel casing. The 10-inch diameter casing shall be pulled back to 3 feet above the well screen while backfilling with the clean, concrete sand. During the sand backfilling the casing shall not be pulled back above the top of the sand.

G. After placement of the sand backfill, Contractor shall settle the backfill around the well point by pumping water from the PVC well screen. Sufficient sand shall be added to the annular space to maintain the level of sand backfill at 5 feet above the top of the well screen. Pumping shall continue intermittently until the discharge water is clear and soil free or until pumping is stopped by Purchaser's representative. Disposal of water discharged from the monitoring well during pumping shall be as directed by Purchaser.

H. After settlement of the sand backfill, place two feet of bentonite in the annular space between the CPVC casing and the outer casing to prevent any movement of the cement grout into the granular backfill. If granular bentonite is used, it shall be placed through a conductor pipe using the tremie or other method as approved by the Purchaser. If bentonite pellets are used, they may be allowed to settle through the water around the CPVC casing. If the water table is below the bentonite seal, add clear water during this process to hydrate the bentonite. When bentonite pellets are used, sufficient length of time shall be allowed for the bentonite to form a seal over the sand backfill before placing grout. After placement and hydration of the bentonite seal, the outer casing shall be pulled to one foot below the top of the bentonite seal.

I. After placement of the bentonite seal, Contractor shall fill the remaining annular space between the CPVC casing and borehole with cement-bentonite grout, placed by the tremie method from the bottom upward or by an alternative method approved by Purchaser. The 10-inch steel casing shall be pulled simultaneously with placement of the grout. A positive head of grout shall be maintained in the temporary casing at all times during the placement. The grout mix shall be approximately 7 gallons of water with 3 pounds of powdered bentonite per 94-pound sack of Portland cement. The bentonite and water shall be mixed first to provide a smooth slurry, then the cement shall be added to the slurry and blended to a smooth consistency.

J. Contractor shall terminate the CPVC casing 3 feet above grade and shall install a vented, removable PVC cap such that the CPVC casing is not restricted by the cap or coupling. Contractor shall cut a small notch in the rim of the CPVC casing to mark the point from which all level measurements are to be made. This point shall be clearly marked on the CPVC casing with an indelible marking.

K. Contractor shall install a 6-foot length of 8-inch diameter protective steel casing 3 feet into the cement-bentonite grout. Contractor shall fill the annular space between casings with cement-bentonite grout to within 6 inches of the top of the CPVC casing. A threaded steel cap with ventilation hole shall be provided for the protective casing. An 18-inch long rebar shall be welded to the top of the steel cap to facilitate its removal during groundwater sampling. Contractor shall paint the protective casing and its cap with florescent type paint. Contractor shall clearly and permanently mark the protective casing with the appropriate alphanumeric designation.

L. Contractor shall construct a concrete apron at the ground surface to provide drainage away from the monitoring well, to prevent movement of water down the side of the steel casing, to prevent erosion, and to provide permanence to the monitoring well. The concrete apron shall be at least 2 feet in diameter and 6 inches in thickness.

M. After the monitoring wells are installed, Contractor shall survey the locations and the elevations of the measuring points on the well casings.

V. DISINFECTION OF WELLS

A. Immediately after completion of well, disinfect it by circulating a chlorine solution through the well, let set for the period specified, then pump the solution from the well, and discharge it as directed.

B. Disinfecting Agent:

a. The disinfecting agentt shall be liquid sodium hypochlorite, NaOCl, or granular calcium hypochlorite, $Ca(ClO)_2$. Calcium hypochlorite shall not be used where the concentration of calcium in the groundwater will exceed 300 ppm after addition of the disinfecting solution. The choice of disinfecting agent is subject to approval by the Consulting Engineer.

b. The disinfecting agent used in the solution shall be delivered to the Project Site in the original, unopened dated containers. Prior to use, the disinfecting agent shall not be exposed to air or direct sunlight.

C. Disinfection Procedure:

a. Determine depth to water and depth to the bottom of the well from a common measuring point. Calculate the height of the water column in the well (depth to bottom of well minus depth to water, in feet).

b. Calculate the total volume of water ($V=V_1+V_2$) in both the well (V_1 in gallons) and sand pack (V_2 in gallons) where V (in gallons) equals the height of the water column times 1.5.

c. With the pump intake located as near the water level as possible, pump the well to remove at least 5 volumes of water, 5x(V). Pump until discharge water is clear. Then, lower the pump intake to the bottom of the well. Pump at least 1.5 volumes of water, 1.5x(V), until discharge water is clear. Additional pumping levels may be required at the discretion of the Consulting Engineer. This step may be deleted if disinfection is performed immediately after well installation.

d. Mix a solution of disinfectant by adding a measured amount of calcium or sodium hypochlorite to a known volume of clear water to provide at least a 200 ppm chlorine solution when mixed with the total volume, V, of water in the well. The amount of disinfecting agent to be added to clear water depends on the initial concentration of hypochlorite. The volume of clear water added shall be no less than the total volume of water, V.

e. After approval of the disinfection solution mix by the Consulting Engineer, place the solution in the well in such a manner that it is thoroughly distributed throughout the entire column of water in the well. Add an extra dosage to the bottom of the well. Make certain that the dry portion of the well casing above the water level is also wetted. This may be accomplished by tremie or by pumping the solution through a hose moved through the well from the bottom up, or by another acceptable method as approved by the Consulting Engineer. Well disinfection by pouring the solution from the top of the well is not acceptable.

f. Recirculate the solution in the well by pumping from the bottom of the well and reintroducing the discharged solution into the top of the well. During recirculation, the portion of the well casing above the water table shall be maintained in a wet condition with the solution. The length of the recirculation period will be determined by the Consulting Engineer, but will not be less than 30 minutes nor more than two hours. Measure the residual free chlorine concentration at the end of the recirculation period.

g. After recirculation, the solution shall remain in the well for a minimum of eight hours. Replace the well caps for this period.

h. After the eight hour or longer period, the well shall be pumped to clean it of solution. Purchaser will determine the residual free chlorine concentration at the beginning of pumping to assure that complete disinfection has occurred. The method of determining the concentration shall be approved by the Consulting Engineer.

i. If the residual free chlorine concentration is greater than or equal to 1.0 ppm, the disinfection of the well will be assumed to be complete. The well shall then be pumped for at least two hours, but not more than four hours, to remove the solution from the well and surrounding aquifer. Vary the depth of the pump intake in the well while pumping, from the top of the water column to the bottom of the well, and back to the top again. Dispose of the water pumped from the well as directed by Purchaser.

j. If the residual free chlorine concentration is less than 1.0 ppm, pump the solution from the well as indicated in step "c." above and repeat the disinfection procedure.

Dear Mr. Scott:

Enclosed are two copies of the Wastewater Ponds Permit Data Report which has been revised per your letter, dated December 20, to Mr. F. J. Emmett. The revisions address overflows from the ponds which are not bounded by the permit. The revisions have been indicated in the righthand margin with an "R". Please review the revisions and return any comments you have to us so that we can reissue the appropriate number of copies for your use.

Yours very truly,

HENRY W. PIRKEY POWER PLANT
DESIGN SUMMARY FOR LIGNITE STORAGE AREA AND WASTEWATER POND FACILITIES

SOUTHWESTERN ELECTRIC POWER COMPANY

I INTRODUCTION

This report is prepared by Sargent & Lundy (S&L) at Southwestern Electric Power Company's (SWEPCO) request to summarize the design of the lignite storage area and the wastewater pond facilities with regard to technical guidelines and requirements of the Texas Department of Water Resources (TDWR). The technical guidelines referenced in this report are Technical Guide Nos. 4 and 6 titled Ponds and Lagoons, and Monitoring/Leachate Collection Systems respectively. Guide No. 4 was revised March 1, 1978 and Guide No. 6 March 21, 1980. We understand that the TDWR has the responsibility of preparing and issuing document approval for disposal of wastes. Requirements concerning waste storage and disposal and concerning the design, construction, and monitoring of wastewater pond facilities are discussed in this report.

The wastewater pond facilities discussed in this report and shown in Exhibit 1 are the lignite pile runoff basin, surge pond, two bottom ash storage basins, secondary settling pond, and the metal cleaning waste pond. Discussion of other waste treatment facilities such as the sanitary sewage treatment plant, the cooling pond, and the final treated Flue Gas Desulfurization (FGD) sludge disposal site are not within the scope of this report and, therefore, not included.

II SUMMARY AND CONCLUSIONS

Based on the evaluation of the site subsurface soil and water conditions, it is concluded that the design of the Henry W. Pirkey wastewater ponds conforms with the technical guidelines and requirements of the TDWR.

Nine groundwater monitoring wells will be located adjacent to the wastewater ponds. These wells will be designed and installed to requirements equal to or exceeding those suggested by the TDWR.

A summary of design guidelines and requirements suggested by the TDWR and those used for design of the Henry W. Pirkey wastewater ponds is given in Exhibit 2.

III DESIGN OF LIGNITE STORAGE AREA AND WASTEWATER POND FACILITIES

A. General

The general site layout is shown in Exhibit 1. The plant water usage and waste water scheme is shown on Exhibit 3. The lignite storage area, lignite pile runoff basin, metal cleaning waste pond, and the surge pond have been sized to accommodate two units. Each bottom ash basin will accommodate storage of hydraulically placed ash for two units for 6 months. When one bottom ash basin is filled, storage will begin in the second basin while the first basin is being emptied and readied for reuse. The in-service bottom ash basin will also receive the discharge from the ash hopper pit sump pumps.

Effluent from the bottom ash basins will discharge to the secondary settling pond. Blowdown from the main and auxiliary boilers will also be routed to the secondary pond. Water collected in the secondary settling pond will be recirculated back to the plant to transport bottom ash. R

The ash basins and secondary pond, acting as a system, have been provided with additional capacity above the normal operating level to capture and hold the 10 year-24 hour runoff from the basin and pond drainage areas. A spillway has been R provided for the secondary pond to discharge inflows in excess of the 10 year-24 hour runoff in conformance with the NPDES permit. The quality of those overflows is not subject to permit limitations. To protect the basin and pond dikes from damage, the spillway has been designed to discharge excess runoff from the 100 year-24 hour runoff and freeboard has been provided above the maximum water level resulting from the 100 year-24 hour runoff. Excess water accumulated in the secondary pond due to rainfall runoff will be pumped to the wastewater treatment plant for treatment prior to discharge.

Drainage from the lignite and limestone storage areas and handling systems will be collected via ditches and routed to the lignite pile runoff basin.

The lignite pile runoff basin has been designed to capture and hold the entire 10 year-24 hour runoff from the basin drainage area with no outflow. An auxiliary spillway has been provided to discharge inflows in excess of the 10 year-24 hour runoff in conformance with the NPDES permit. The quality of these overflows is not subject to permit limitations. To protect basin dikes from damage due to overflow, the spillway has been designed to discharge excess runoff from the 100 year-24 hour runoff and freeboard has been provided above the maximum water level due to the 100 year-24 hour runoff.

Water captured in the lignite pile runoff basin will not normally require more treatment than sedimentation to lower the total suspended solids content prior to release. Once the suspended solids are within acceptable limits, the basin contents will be discharged to the cooling pond by gravity in a normally closed pipe outlet. However, if treatment other than gravity settling is required, the contents of the lignite pile runoff basin will be pumped to the wastewater treatment plant prior to release.

The surge pond is divided into two sections: the main surge pond and the auxiliary surge pond. The auxiliary surge pond is a collection and settling pond for scrubber waste slurry, from the FGD system waste slurry pumps, thickener underflow pumps, and filtrate overflow sump pumps. These slurry flows will be routed to the auxiliary surge pond only under emergency conditions and allowed to thicken by gravity settling. The sludge formed when the slurry thickens will be removed by front end loader and conveyed to the sludge treatment system for stabilization. The water decanted from the thickened slurry, and not evaporated, will overflow to the surge pond.

The main surge pond is a collection basin for overflows from the auxiliary surge pond and several additional waste streams. Surface drainage from the FGD system and the reclaim water sump overflow will also drain into the surge pond. Rainwater runoff from the sludge truck load out area, from under the sludge conveyors, and from the sludge reclaim area will drain to the surge pond by gravity. The water decanted from the auxiliary surge pond will drain to the surge pond. The collected water in the surge pond will be pumped to the thickeners for removal of sediment and used as make-up for the SO_2 scrubbers. Drainage entering the surge pond will not leave the plant except as makeup to the scrubbers, as water hydrated with the stabilized FGD sludge, or through evaporation.

Waste from air heater wash, precipitator wash and boiler chemical cleaning is discharged to the metal cleaning pond for storage. This pond is designed to accommodate all the wastewater containing heavy metals generated in 24 hours by cleaning all the three air heaters associated with one unit. Water collected in the metal cleaning waste pond will be pumped to the waste water treatment system for processing before being discharged to the cooling pond.

B. Lignite Storage Area and Runoff Basin Design

The location and layout of the lignite storage area and lignite pile runoff basin are shown on Exhibit 1. Five borings have been drilled in this area and their locations are shown on Exhibits 4 and 5. Copies of the boring logs are included in Appendix A. Based on the results of the boring data, the lignite storage area and lignite pile runoff basin are located over surface soil deposits of dense silty sand and sandy silt (SM and ML Unified Soil Classification). A summary of the laboratory test results on samples from these borings is given in Exhibit 6. All soil borings and soil laboratory test results given in this report, with the exception of Boring B14, have been drilled and tested by NFS/National Soil Services, Inc., Dallas, Texas. Boring B14 was drilled and tested by East Texas Testing Laboratory, Inc., Tyler, Texas. Complete laboratory index property and permeability test results for all samples from borings located in or near wastewater pond facilities are included in Exhibit 6. Also included for reference are index property and permeability values for various types of soils from other onsite borings.

The lignite pile runoff basin is an above and below ground pond designed to store lignite pile and limestone pile runoff. Plan and cross sections are shown in Exhibit 5. The lignite storage pile will be underlain by two feet of compacted cohesive fill (SC, CL, and CH Unified Soil Classification). The drainage ditches transporting runoff from the storage area to the basin will be lined with minimum 18 inches of compacted cohesive fill. The runoff basin will be lined on the bottom and side slopes with a minimum three feet of compacted cohesive fill. The dike fill, including lining, will be compacted as specified to a minimum 95 percent maximum density in accordance with ASTM D698. These requirements are in accordance with the guidelines suggested by the TDWR for wastewater ponds.

A summary of the parameters used for the lignite pile runoff basin design in comparison to those parameters and guidelines suggested by the TDWR is given in Exhibit 2. The runoff basin design parameters equal or exceed the minimum recommended values except for depth to the water table. Average or median parameter values are given where several individual tests or measurements were made. The only suggested parameter not obtainable is the TDWR recommendation that the bottom of the basin be 10 feet above the water table. The water table varies throughout the site, and with normal pool of the cooling pond at elevation 340.0 ft., it is possible that the static water table may be located within 3 feet of the bottom of the clay lining of any of the plant's wastewater ponds. Despite this, the presence of relatively homogeneous impermeable in situ and compacted clay layers should provide sufficient lining and protection of the groundwater.

Compacted clay linings are required on the bottom and side slopes of the lignite pile runoff basin and beneath the lignite storage pile. Project specifications require these compacted linings to be cohesive soils with minimum 40% passing the no. 200 sieve and having a minimum plasticity index of 15. The linings are to be compacted to minimum 95% maximum density in accordance with ASTM D698. The permeability of the compacted linings is estimated to be less permeable than or equal to 1.0×10^{-7} cm/sec. This will be verified by SWEPCO by testing field samples in the laboratory during or after construction.

C. Surge Pond Design

The location and layout of the surge pond are shown on Exhibit 1. Four borings have been drilled in this area and their locations are shown on Exhibits 4 and 7. Copies of the boring logs are included in Appendix A. Based on the results of the boring data, the surge pond is located within or above a thick surface deposit of silty and sandy clay (CL and CH Unified Soil Classification). The thickness of the in situ clay soils below the bottom of the pond (approximately elevation 350 ft) ranges from two and one half to 16 feet. A summary of the laboratory test results on samples from the surge pond borings is given in Exhibit 6.

The surge pond (including auxiliary surge pond) is an above and below ground pond. Dikes and excavated slopes are designed with three horizontal to one vertical side slopes. Dike fill will be cohesive soil compacted to a minimum 95 percent maximum density in accordance with ASTM D698. Typical surge pond cross sections are shown on Exhibit 7.

In situ cohesive soils will be used to function as the pond lining. Verification of the quality and thickness of the in situ lining will be made during or after construction by SWEPCO. As previously stated, the borings indicate that the thickness of the in situ lining ranges from approximately two and one half to 16 feet. Any compacted cohesive linings required will meet the density, index property, and permeability requirements as given for the lignite runoff basin.

Exhibit 2 summarizes the TDWR suggested parameters and guidelines and those parameters used for the surge pond design. Comparison of the design parameters obtained and those suggested indicate that in almost every case the obtained parameters equaled or exceeded the suggested value. The only suggested parameter not obtainable is the recommended 10 ft. depth to the groundwater table. It is possible that the groundwater table could eventually be located within 3 ft. of the bottom of the clay lining of the pond, as previously discussed.

Six laboratory permeability tests were performed on samples of undisturbed clay soil from the surge pond area. Results are given in Exhibit 8 and indicate a median permeability value of $5.1\text{x}10^{-8}$ cm/sec. The permeability test values ranged from $2.1\text{x}10^{-6}$ cm/sec. to $7.4\text{x}10^{-9}$ cm/sec.

D. <u>Bottom Ash Basin and Secondary Pond Design</u>

The location and layout of the bottom ash basins and secondary pond are shown on Exhibit 1. Plan and cross sections are shown in Exhibit 9. Nine borings have been drilled in this area. Their locations are given in Exhibits 4 and 9. Copies of the boring logs are included in Appendix A. Based on the results of the boring data, the secondary pond, bottom ash basin no. 1 and the east half of bottom ash basin no. 2 are located within or above a thick surface deposit of silty and sandy clay. These soils are classified as SC, CL, and CH material. A summary of the laboratory test results on samples from those borings is given in Exhibit 6. Results of approximately 23 tests on cohesive soils representing in situ lining indicate average fines content and plasticity index values of 78% and 36, respectively. These values significantly exceed the minimum values suggested by the TDWR.

Bottom ash basin no. 1 is an above and below ground pond located entirely in a cohesive soil deposit. The thickness of the cohesive soil below the bottom of the pond is greater than 5 feet. The plan and cross sections are given in Exhibit 9. A compacted clay lining is shown and will be used where required. In situ lining of acceptable quality and thickness exist in most of the area. This will be verified in the field during construction by SWEPCO. Shallow borings, test pits, and laboratory testing will be performed as necessary.

Bottom ash basin no. 2 is also an above and below ground pond. A portion of this pond (west half) will require a minimum three feet thick compacted clay lining. The location where an acceptable in situ lining does not exist and where the compacted lining begins will be determined and verified in the field by SWEPCO.

The secondary pond has a bottom elevation of 344 feet. This is three feet or more below the lowest point in either bottom ash basin. During borrow excavation and construction of the embankment, the existing clay may be completely removed from areas within the pond. Where this occurs, a three foot thick compacted clay lining will be installed to the requirements of project specifications and the technical guidelines suggested by the TDWR. This will be verified in the field by SWEPCO.

Exhibit 2 summarizes the TDWR parameters and guidelines and those parameters used for the design of the bottom ash basins and the secondary pond. As indicated in Exhibit 2, the design parameters meet or exceed nearly all of the suggested values. The only suggested parameter not obtainable is the recommended depth to the groundwater table as previously discussed. The median permeability from ten laboratory tests on samples of in situ cohesive soils (generally CH classification) is approximately $7.5\text{x}10^{-9}$ cm/sec. The permeability of clay soils used for compacted cohesive linings (SC, CL, and CH classification) is estimated to be less than or equal to $1.0\text{x}10^{-7}$ cm/sec. The permeability of the compacted lining will be verified by SWEPCO by testing field samples in the laboratory during and after construction.

E. Metal Cleaning Waste Pond

The location and layout of the metal cleaning waste pond are shown on Exhibit 1 and 10. The pond lies between the surge pond and the bottom ash basins. Borings located near the metal cleaning waste pond are shown in Exhibit 4. Review of the boring data indicates that the pond is located within or above a thick surface deposit of silty and sandy clay. Evaluation of the boring data is similar to that of the bottom ash basins.

The metal cleaning waste basin is an above and below ground pond. Plan and cross sections are given in Exhibit 10. The pond will require a minimum three feet thick clay lining where sufficient in situ clay does not exist at the design elevation. SWEPCO will verify the quality and acceptability of the lining, whether in situ or compacted.

IV GROUNDWATER MONITORING PROGRAM

Nine groundwater monitoring wells are to be installed at locations adjacent to the wastewater pond facilities. The wells will be installed after completion of pond construction. The approximate locations of these wells are given in Exhibit 12.

Four-inch diameter monitoring wells will be used because they permit use of a portable submersible pump for obtaining samples for water quality analysis. Each slotted screen for each well will be located in the most permeable soils occurring below the water table. A soil boring will be drilled at each well location to accurately define the soil strata adjacent to the well and to finalize the location and design of the well. The soils are very dense and range from a medium fine sand and silty sand to clayey sand and silty clay. The length of the screens have not yet been determined but are expected to range from 15 to 25 feet.

Technical Guide No. 6, published by the TDWR, presents guidelines for design and installation of monitoring wells. The H. W. Pirkey monitoring wells will equal or exceed these guidelines.

The groundwater monitoring program will consist of measuring and recording groundwater levels and obtaining samples for water quality analysis. The frequency for measuring levels and obtaining samples has not yet been determined. Measurements and samples will be obtained by SWEPCO and should begin at least two years before the power plant begins operation. This will allow for sufficient background data against which to compare all subsequent measurements and analyses of samples taken at the site.

Wastewater Ponds - Liner
Verification & Monitoring Wells

Mr. M. J. Scott
Southwestern Electric Power Company
P. O. Box 21106
Shreveport, Louisiana 71156

Dear Mr. Scott:

We have completed our review of the boring logs and results of the laboratory tests made on samples from the borings which you transmitted to us. This work was performed as part of the liner verification program transmitted to Mr. R. A. Neal with a letter, dated February 25, 1983.

Enclosed is a copy of Table #1 which was developed by combining the information contained on the field logs and the results of the laboratory test data. From the information contained in Table #1, Table #2 was prepared and summarizes our analysis of the test results for each individual pond or lined area.

Our analysis indicates that the cohesive linings for the surge pond, metal cleaning waste pond, bottom ash basins No. 1 and No. 2 and beneath the lignite storage pile are in general accordance with the guidelines suggested by the Texas Department of Water Resources. The average permeability reported for bottom ash basin No. 1 is 2.4×10^{-6} cm/sec. This value is higher than desired because it is significantly influenced by one out of the eight tests run. This one test yielded a 1.1×10^{-5} cm/sec flow rate for a CH clay sample which leads one to believe that the test may be in error due to a leak in the testing apparatus or a miscalculation. You may want to run this by the laboratory for a check.

SWL
&
SL

COPY

The cohesive lining for the secondary pond appears to be very sandy or contains sand pockets more so on the east side of the pond. The area should be inspected and repaired if necessary to improve its cohesive lining.

done

The borings and testing for the lignite pile runoff basin was not yet completed when you transmitted the data. Please forward this data to us as soon as it becomes available so that the tables can be completed. Also boring S-17 in the Metal Cleaning Pond was not yet drilled.

done
S-15
wk. of 10/8

Part of this verification program was also to consist of a review of the field density test records for the lining made during construction so that a statistical summary could be performed. This data was included in your previous transmittal. Please forward us this data at your convenience.

SWEPCO

We have also enclosed a marked up copy of the boring logs correcting the soil classification based on our review of the laboratory test data. Please have the laboratory make the indicated corrections and re-issue the logs.

SWL

We also received the boring logs for the ten monitoring wells. A review of these logs indicates that if the wells are installed per the detail proposed in the monitoring well program, they will encounter pervious sandy soils. Well MW-9 may, however, need to be installed approximately five feet deeper than proposed to intersect a thicker layer of sands.

SWL
& StL

After you review the data being transmitted to you and with your concurrence we will formalize the data into an Appendix which can be added to the Wastewater Pond Data Report.

Yours very truly,

Southwestern Electric Power Company

FOR COMPANY BUSINESS ONLY

SUBJECT Waste Water Ponds Lining Verification and Monitoring Wells

DATE February 6, 1984

LOCATION Henry W. Pirkey Power Plant, Unit #1

Mr. Jay Pruett

Attached please find one copy of the "Waste Water Ponds Lining Verification and Monitoring Wells" report of work performed to date. In order to complete this project, the following must be accomplished:

A. perform borings S-21 and S-22 in lignite pile run-off basin

B. perform boring S-15 in metal waste cleaning pond

C. re-drill borings S-1, S-2 and S-3 in secondary pond.

This work will be performed during the summer of 1984.

Please advise if you have any comments regarding this report.

W. H. Holley

Gentlemen:

Enclosed is our Subsurface Exploration Report on Borings S-1, S-2 and S-3. These are redrilled for verification of the lining for the pond. The locations of the borings are shown on your drawing number HP-56A.

It has been a pleasure to perform this work for you. If, during the course of this project, we can be of any further assistance, please do not hesitate to call on us.

Very truly yours,

Gentlemen:

The above referenced report was dated October 5, 1983. In accordance with Bill Porter's request dated December 22, I have revised the boring schedule for this report.

These revisions are based on the revised survey by Hart Engineering which was reported to you on October 11, 1983, by Mr. Nealy of Hart Engineering.

Data on the following borings was revised: S-10, S-11, MW-2, MW-4 and MW-10.

Very truly yours,

SOUTHWESTERN LABORATORIES

Gentlemen:

Enclosed is our Summary of Laboratory Test Data and Log of Boring for Boring MW-3 of the above referenced project.

To summarize, all borings for this project have been completed, with the exception of S-15, S-21, and S-22, and the re-drills of S-1, S-2, and S-3. These borings are on indefinite hold at you request.

The ten (10) monitor wells have been installed. However, the steel protective caps have not been installed.

It has been a pleasure to perform this work for you. If we can be of any further assistance, please do not hesitate to call on us.

Very truly yours,

SPEC. H-4533

GENERAL NOTES

1. ALL WORK SHOWN ON THIS DRAWING AND ON DRAWINGS REFERRED TO THESE GENERAL NOTES SHALL BE DONE BY THE EARTHWORK CONTRACTOR IN ACCORDANCE WITH SPEC. H-4533 UNLESS NOTED OTHERWISE.
2. ALL FILL MATERIALS FOR DIKE WORK AND POND LINING SHALL BE OBTAINED FROM SITEWORK EXCAVATION. WHEN ENOUGH SUITABLE MATERIAL IS NOT AVAILABLE, BORROW MATERIALS SHALL BE OBTAINED FROM AREAS INDICATED ON THE DRAWINGS OR FROM AREAS APPROVED BY OWNER.
3. AREAS UNDER THE DIKES SHALL BE STRIPPED TO A MINIMUM OF ONE FOOT, OR AS REQUIRED BY OWNER.
4. TOPSOIL SHALL BE STOCKPILED IN AREAS APPROVED BY OWNER.
5. ALL SPOILS SHALL BE DISPOSED IN THE AREA SHOWN ON THE DRAWING OR IN OTHER AREAS APPROVED BY OWNER.
6. ALL ELEVATIONS SHOWN ON THE DRAWINGS ARE FINISHED GRADE ELEVATIONS UNLESS NOTED OTHERWISE.
7. ALL DRAINAGE DITCHES SHALL BE PROVIDED WITH 4 INCHES OF SEEDED TOPSOIL, UNLESS NOTED OTHERWISE.
8. ALL CONCRETE RIPRAP SHALL BE OF "CLASS B CONCRETE" AS SPECIFIED FOR "CONCRETE FOR STRUCTURES" IN ITEM 421 AND ITS REINFORCING SHALL BE 6"x6"x W2.1 x W2.1 WIRE MESH, AS SPECIFIED IN ARTICAL 432.9 OF ITEM 432 OF "TEXAS HIGHWAY DEPARTMENT" 1972 STANDARD SPECIFICATION FOR CONSTRUCTION OF HIGHWAYS, STREETS & BRIDGES.
9. ALL CULVERT PIPES SHALL BE BITUMINOUS COATED CORRUGATED METAL PIPE (C.M.P.) WITH 2⅔"x½" CORRUGATION, UNLESS NOTED.
10. FOR SOIL CEMENT DETAIL, SEE DRAWING C-34.
11. THE SURGE POND, ASH BASINS AND SECONDARY POND SHALL BE EXCAVATED TO THE FINISHED GRADE INDICATED. PURCHASER AND/OR CONSULTING ENGINEER SHALL VERIFY ACCEPTABILITY OF THE INSITU POND BOTTOM. IF THE INSITU MATERIAL IS ACCEPTABLE, NO FURTHER EXCAVATION WILL BE NECESSARY. IF THE INSITU MATERIAL IS NOT ACCEPTABLE EXCAVATE A SUFFICIENT AMOUNT OF MATERIAL SO THAT A 3'-0" THICK COMPACTED COHESIVE LINING CAN BE INSTALLED TO BRING THE BOTTOM OF THE POND UP TO THE FINISHED GRADE INDICATED ON THESE DRAWINGS.
12. ALL FILL SLOPES & CUT SLOPES SHALL BE PROVIDED WITH 4" SEEDED TOPSOIL UNLESS NOTED OTHERWISE.
13. TYPE OF FILTER FABRIC SHALL BE APPROVED BY PURCHASER AND INSTALLED PER MANUFACTURES REQUIREMENT.

RE: West Ash and East Ash Pond – Hydrology and Hydraulic Analysis
Pirkey Power Generating Station
Hallsville, Texas

Dear Mr. Dreger:

Auckland Consulting, LLC (Auckland) is pleased to provide the attached Hydrology and Hydraulic Report for both the West Ash and East Ash Ponds located at the Pirkey Power Generating Station near Hallsville, Texas. The analysis covers both the 25-year, 24-hour and 100-year, 24-hour storm events as required by 40 CFR §257.82(a). As indicated through various phone conversations and email correspondence, the West Ash and East Ash Ponds were identified as the only CCR impoundments requiring this demonstration.

Please do not hesitate to contact us with any questions or comments.

Best regards,

John J. Tayntor, P.E.
Auckland Consulting LLC

HYDROLOGIC & HYDRAULIC CALCULATIONS

APPENDIX - A

Introduction

H.W. Pirkey Power Plant which is located in Hallsville, Texas is a subsidiary of American Electric Power. Plant operation requires a series of water impoundments utilized in the process of power generation, including the bottom ash ponds. The purpose of this report is to analyze and document the Hydrologic & Hydraulic characteristics of the East and West Bottom Ash Ponds at Pirkey Power Plant.

Hydrologic Methodology

This section describes the general outline of the hydrologic methodologies used to evaluate the total runoff tributary to the ponds. Specific characteristics of each pond are discussed under individual subheadings later in this report.

The East & West Ash Ponds are total containment ponds. Watershed areas contributing to the flow into these ponds are the ponds and berms/access roads themselves; in other words, these ponds have no additional runoff areas tributary to them. Therefore, a conservative approach is to adopt a curve number 100 and to consider that every inch of rainfall will directly increase the water surface elevation.

According to Natural Resource Conservation Service (formerly SCS) Technical Release 55, the peak flow is calculated using the formula:

$Q = (P-0.2S)^2 / (P+0.8S)$

where,

Q = runoff (inches)

P = rainfall (inches)

S = potential maximum retention after runoff begins (inches) = (1000/curve number) – 10

Applying a curve number of 100 to the formula above will ultimately result in $Q = P$ (because $S=0$); which implies that the total runoff contributing to the flow in each of the ponds is directly a function of the rainfall event.

Hydraulic Methodology

This section describes the general outline of the hydraulic methodologies used to analyze the storage capacity of the ponds. Specific characteristics of each pond are discussed under individual subheadings later in this report.

The plant's CCR rules require that the ponds be able to accommodate the rainfall volume from a

100 year 24 hour storm without over topping. The normal operating level for each pond is established by other regulations, and it is set to 3 feet below the top of the embankment. Using actual field survey data, an elevation-area-storage table was developed for the ponds and is included in the tables section of this report. Hydraflow Hydrographs was utilized to evaluate storage capacity and the water surface elevations in each pond during the 100 year 24 hour rainfall event. The 25 year 24 hour rainfall event was analyzed as well.

Detailed Hydrologic & Hydraulic characteristics of the ponds are discussed below.

EAST ASH POND:

The East Ash Pond is located to the east of the rail road track and north of the Pirkey Power Plant. This is a coal combustion waste pond used to settle bottom ash that has been sluiced from the plant boiler. Field survey of the embankment around the impoundment indicates that the top of the embankment is at a minimum elevation of 357.0msl, which is consistent with original design drawings. Therefore, based on this top of embankment elevation, the normal operating level was established at 354.0msl. The watershed area contributing to the flow into this pond was estimated to be 29.63 acres.

The storage capacity for each pond was analyzed for a 100-yr, 24-hr rainfall event, which is 10.3 inches. Multiplying the acreage times the inches, the calculated volume of the rainfall event is 1,107,836 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 1,142,455 cf.

The storage capacity was also analyzed for a 25-yr, 24-hr rainfall event, which is 8.2 inches. The calculated volume of the rainfall event is 881,967 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 909,528 cf.

Water surface elevation was then calculated for the 100-yr, 24-hr rainfall event with a normal operating level (354.0msl) as the baseline elevation. Results from Hydraflow Hydrograph indicates that the water surface elevation during the 100-yr, 24-hr rainfall will be 354.99msl which is less than 357.0msl (embankment top). Results from the 25-yr, 24-hr rainfall event indicate the water surface elevation will be 354.79msl which is also less than 357.0msl (embankment top).

WEST ASH POND:

The West Ash Pond is located to the west of the rail road track and adjacent to the east ash pond. This is a coal combustion waste pond used to settle bottom ash that has been sluiced from the plant boiler. Field survey of the embankment around the impoundment indicates that the top of the embankment is at a minimum elevation of 357.0msl, which is consistent with original design drawings. Therefore, based on this top of embankment elevation, the normal operating level was established at 354.0msl. The watershed area contributing to the flow into this pond was estimated to be 33.44 acres.

As mentioned earlier the storage capacity for each pond was analyzed for a 100-yr, 24-hr rainfall event, which is 10.3 inches. Multiplying the acreage times the inches, the calculated volume of the rainfall event is 1,250,228 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 1,289,360 cf.

The storage capacity was also analyzed for a 25-yr, 24-hr rainfall event, which is 8.2 inches. The calculated volume of the rainfall event is 995,376 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 1,026,480 cf.

Water surface elevation was then calculated for the 100-yr, 24-hr rainfall event with a normal operating level (354.0msl) as the baseline elevation. Results from Hydraflow Hydrograph indicates that the water surface elevation during the 100-yr, 24-hr rainfall will be 355.01msl which is less than 357.0msl (embankment top). Results from the 25-yr, 24-hr rainfall event indicate the water surface elevation will be 354.81msl which is also less than 357.0msl (embankment top).

Summary

Water surface elevations calculated from Hydraflow Hydrographs are tabulated below:

SUMMARY OF POND HYDRAULIC CHARACTERISTICS				
	TOP OF EMBANKMENT	OPERATING LEVEL	100YR-24HR WSEL	25YR-24HR WSEL
EAST ASH POND	357.0	354.0	354.99	354.79
WEST ASH POND	357.0	354.0	355.01	354.81

As evident from the table above, it is the opinion of Akron Consulting that the East & West Ash Ponds will serve to adequately contain the calculated rainfall events.

Table of CONTENTS

1.0 OBJECTIVE 257.73(d)

This report was prepared by AEP- Geotechnical Engineering Services (GES) section to fulfill requirements of 30 TAC 352.731 (40 CFR 257.73(d)) and document whether the design, construction, operations, and maintenance of the CCR unit is consistent with recognized and generally accepted good engineering practices. This is the first periodic 5-year review of the initial assessment as per the rule.

Note: There has not been any changes to the diking structures or the discharge weir boxes and discharge pipes passing through the dikes since the initial assessment.

2.0 NAME AND DESCRIPTION OF CCR SURFACE IMPOUNDMENT

The Henry W. Pirkey Power Station is located at 2400 FM 3251 and south of Hallsville, Texas. It is owned and operated by Southwest Electric Power Company (SWEPCO). The facility operates two surface impoundments for storing CCR materials called the East Bottom Ash Pond (East BAP) and the West Bottom Ash Pond (West BAP).

The East BAP is located directly adjacent to and east of the West BAP. The East BAP receives sluiced bottom ash and has a surface area of 30.9 acres and a storage capacity of 188 acre-feet. The pond is almost entirely incised, with a reported maximum embankment height of 4 feet.

The West BAP, which also receives sluiced bottom ash, is located northwest of the main plant and shares its eastern border with the western border of the East BAP. The West BAP receives sluiced bottom ash and has a surface area of 30 acres and a storage capacity of 188 acre-feet. The maximum embankment height is 25 feet. Design documents indicate that the main upstream embankment slopes are 3 feet horizontal to 1 foot vertical (3:1 H:V); while the main downstream slopes are 2.5:1 H:V.

3.0 STABLE FOUNDATION AND ABUTMENTS 257.73(d)(1)(i)

[Was the facility designed for and constructed on stable foundations and abutments? Describe any foundation improvements required as part of construction.]

The foundaion materials for the East BAP are native soils which consist of stiff to very stiff sandy lean clay (CL) and sandy fat clay (CH) with intermittent layers of medium dense to dense silty sand (SM) and clayey sand (SC). Atterberg Plasticity Indices of tested soils ranged between a low of 16 to a high of 39. Based on the subsurface investigation and engineering properties of the subsurface soils, it is concluded that the East Bottom Ash Pond dikes are supported on a stable foundation base.

The foundation materials for the West BAP are native soils which consist primarily of medium dense to very dense clayey sand (SC) with layers of of dense clayey gravel (GC) and very dense silty clayey sand (SC-SM). Atterberg Plasticity Indices of tested soils ranged between a low of 9 to a high of 46. Based on the subsurface investigation and engineering properties of the subsurface soils, it is concluded that the West Bottom Ash Pond dikes are supported on a stable foundation base.

Operation of the impoundment is performed so as to not adversely affect the foundation and abutments. As required by the CCR rules the East and West Bottom Ash Ponds are inspected at least every 7 days by a qualified person. Also as a requirement of the CCR rules, the impoundment is also inspected annually by a professional engineer. Maintenance items are addressed as they are discovered as a part of those inspections.

4.0 SLOPE PROTECTION 257.73(D)(1)(II)

[DESCRIBE THE SLOPE PROTECTION MEASURES ON THE UPSTREAM AND DOWNSTREAM SLOPES.]

The east and west CCR impoundments have a layer of bottom ash on the interior slopes of the ash ponds that provide protection from erosion and wave action. The exterior slopes consist of vegetative cover. Any erosion that may occur is repaired within a timely period.

5.0 EMBANKMENT CONSTRUCTION 257.73 (d)(1)(iii)

[Describe the specifications for compaction and/or recent boring to give a relative comparison of density.]

The East BAP is primarily incised into native soils with an embankment height of approximately 4 feet (AMEC, 2010). The East BAP embankments are constructed of compacted clay on a 3:1 slope (3 feet horizontal, 1 foot vertical) (Sargent & Lundy, 1983). The soils are primarily stiff to very stiff sandy lean clay (CL) and sandy fat clay (CH) with intermittent layers of medium dense to dense silty sand (SM) and clayey sand (SC). The elevation of the top of embankment around the perimeter of the East BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, May 2011). The interior bottom elevation of the East BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Johnson & Pace, June 2011). Based on the subsurface investigation and the engineering properties of the subsurface soils, it is concluded that the East bottom Ash Pond embankments are adequately constructed.

The West BAP embankments have maximum height of approximately 25 feet and are constructed of compacted clay on a slope ranging from 2.5:1 (2.5 feet horizontal, 1 foot vertical) to 3:1 (Sargent & Lundy 1983). The elevation at the top of the embankment around the perimeter of the West BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, 2011). The embankment fill materials are primarily stiff to very stiff lean clay (CL) and/or fat clay (CH), overlying native soils consisting of primarily dense to very dense clayey sand (SC) with layers of dense gravel (GC) and very dense silty clayey sand (SC-SM). The interior bottom elevation of the West BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Akron Consulting, 2012). Based on the slope stability evaluation and the engineering properties of the subsurface soils, it is concluded that the West Bottom Ash Pond embankments are adequately constructed.

6.0 VEGETATION CONTROL 257.73 (d)(1)(iv)

[Describe the maintenance plan for vegetative cover.]

The vegetative slopes/areas are mowed to facilitate inspections and maintain the growth of the vegetative layer; and prevent the growth of woody vegetation.

7.0 SPILLWAY SYSTEM 257.73(d)(1)(v)

[Describe the spillway system and its capacity to pass the Inflow Design Flood as per its Hazard Classification.]

Hydrology and Hydraulic Analysis which includes calculations for each spillway structure are included in Inflow Design Flood Control Plan. The Inflow Design Flood for the East and West Bottom Ash Ponds is the 100-year storm event.

The surface water elevation in the East BAP is controlled by a weir box and a manually operated gate valve installed on a 36-inch diameter discharge pipe at the southwest corner of the pond. Clear water overflow from the East BAP discharges through the 36-inch diameter pipe into a 2.7 acre Clearwater Pond located directly south of the East BAP. Water in the Clearwater Pond is either pumped (re-circulated) back into the boiler ash hopper, the FGD make up system or pumped back to the Sabine mine for beneficial reuse as dust suppression water.

The surface water elevation in the West BAP is controlled by a weir box and a manually operated gate valve installed on a 36-inch-diameter discharge pipe at the southeast corner of the pond. Clear water overflow from the West BAP discharges through the 36-inch diameter pipe into a 2.7 acre Clearwater Pond located southeast of the West BAP. Water in the Clearwater Pond is either pumped (re-circulated) back into the boiler ash hopper, the FGD make up system or pumped back to the Sabine mine for beneficial reuse as dust suppression water.

Based on the Hydrology and Hydraulic analysis the East and West BAP’s spillway system can handle the 100-year storm event.

<u>8.0</u> BURIED HYDRAULIC STRUCTURES 257.73 (d)(1)(vi)

[Describe the condition of the sections of any hydraulic structure that in buried beneath and/or in the embankment.]

Clear water overflow from the East BAP discharges through a 36-inch diameter corrugated steel pipe that passes into a 2.7 acre Clearwater Pond located directly south of the East BAP. The 36-inch diameter corrugated steel pipe passes under the embankment that separates the East Bottom Ash Pond from the clear water pond. In 2012 when the clear Water pond was completely drained exposing the outfall end of the pipe, the 36 CMP appeared to be in stable and functional condition.

Clear water overflow from the West BAP discharges through a 36-inch diameter corrugated steel pipe that passes into a 2.7 acre Clearwater Pond located directly southeast of the West BAP. The 36-inch diameter corrugated steel pipe passes under the embankment that separates the West Bottom Ash Pond from the clear water pond. In 2012 when the clear water pond was completely drained exposing the outfall end of the pipe, the 36 CMP appeared to be in stable and functional condition.

There are no signs of settlement or sinkholes on the ground surface above the pipes. The discharge pipes have not shown signs of excess corrosion or deterioration based on exterior visual inspections since the initial assessment.

<u>9.0</u> SUDDEN DRAWDOWN 257.73 (d)(1)(vii)

[If the downstream slope is susceptible to inundation, discuss the stability due to a sudden drawdown.]

The downstream slopes of the Bottom Ash Pond dikes will not be inundated from any adjacent water bodies. There have not been any changes to the downstream slope areas of the Bottom Ash Ponds since the initial assessment.

Table of CONTENTS

1.0 OBJECTIVE

This report was prepared by AEP- Geotechnical Engineering Services (GES) section to fulfill requirements of 30 TAC 352.731 (40 CFR 257.73(e)) for the safety factor assessment of CCR surface impoundments. This is the first periodic 5-year review of the safety factor assessment.

2.0 DESCRIPTION OF THE CCR UNIT

The Henry W. Pirkey Power Station is located at 2400 FM 3251 and south of Hallsville, Texas. It is owned and operated by Southwest Electric Power Company (SWEPCO). The facility operates two surface impoundments for storing CCR materials called the East Bottom Ash Pond (East BAP) and the West Bottom Ash Pond (West BAP). This report addresses the East Bottom Ash Pond.

The East BAP is located directly adjacent to and east of the West BAP. The East BAP receives sluiced bottom ash and has a surface area of 30.9 acres and a storage capacity of 188 acre-feet. The East BAP is almost entirely incised on three sides with a reported maximum embankment height of 4 feet and a splitter dike on the west side that is shared with the West BAP. Design documents indicate that the main upstream embankment slopes are 3 feet horizontal to 1 foot vertical (3:1 H:V); while the main downstream slopes are 2.5:1 H:V. The East BAP embankments have the same crest width and slopes and are constructed of the same materials with the same compaction and strength characteristics as the West BAP embankments. Since the soil characteristic and foundation conditions of the East BAP are similar to the soil characteristics and foundation conditions of the West BAP, it is concluded that the East BAP embankments would be covered under West BAP stability report titled Initial Safety Factor Assessment – West Bottom Ash Pond. A copy of the West BAP Safety Factor assessment report is attached.

3.0 SAFETY FACTOR ASSESSMENT 257.73(e)

As mentioned above, it was concluded that the safety factor assessment of the East BAP would be covered under the West BAP stability report titled Initial Safety Factor Assessment – West Bottom Ash Pond. Additionally, since the maximum embankment height of the East BAP is 4 feet while the maximum embankment height of the West BAP is 25 feet it is concluded that the factor of safety for the East BAP embankments would be equal to or better than the West BAP embankments. Therefore, the periodic 5-year review was conducted to evaluate if any physical changes have been made to the earthen dike and/or operating changes that could impact the loading on the structure. The assumptions, material properties and operating pools defined in the initial assessment were reviewed. The review concluded that there have been no changes that would impact the stability analyses that were previously conducted. Therefore, the previous report and analyses are still applicable to the current conditions of the facility. The results indicate that the calculated factors of safety meet or exceed the minimum values defined in Section 257.73(e).

Appendix

1.0 Introduction and Embankment Information

1.1 Introduction

The following report and evaluation provides the Initial Safety Factor Assessment of the West Ash Pond, an existing CCR impoundment (as defined by 40 CFR §257.2) located at the Pirkey Power Station near Hallsville, Texas. In accordance with 40 CFR §257.73(e)(1)(i) through (iv) this initial assessment provides field and laboratory data, model outputs (detailing multiple stability conditions) and summary of safety factors for the West Ash Pond. In accordance with 40 CFR §257.73(e)(2) this report provides the Initial Safety Factor Assessment certification for the West Ash Pond.

1.2 Referenced Information and Data

Soils data, comprised of field and laboratory testing, utilized in the preparation of this assessment were completed by ETTL Engineers and Consultants, Inc. and documented in the report *Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas* dated October 12, 2010. Based on a review of the provided field and laboratory data, it appears to be accurate and appropriate for use in the initial structural stability assessment of the West Ash Pond [40 CFR §257.73(e)(1)]. Furthermore, based on a recent site visit (October 2015), no modifications or elevation alterations have been made to the embankment since the referenced investigation. No additional field or laboratory activities were conducted. Soil data utilized in this evaluation is provided in the Appendix of this report.

To supplement existing data collected in the above reference report, an additional eight (8) Cone Penetrometer Test (CPT) soundings were advanced both along the crest and southern toe of the West Ash Pond. Sounding depths ranged between approximately 14 feet and 40 feet before encountering refusal. The data collected generally supports the findings from the 2010 study and confirms that embankment and foundation soils are relatively consistent. The location of and data from these CPT soundings are provided in the Appendix of this report.

The impoundment pool elevation data cited herein were provided in a separate hydrology and hydraulic (H&H) analysis report completed by Akron Consulting, LLC titled *Hydrology & Hydraulic Report, East & West Ash Ponds, H.W. Pirkey Power Plant – Hallsville, Texas,* dated December 15, 2015 (not included herein). The referenced report generally meets the demonstration requirements of 40 CFR §257.82(a).

Embankment profile dimensions and elevations were determined by using existing information provided by the client or representatives of the client. This information is also included in the Appendix of this report.

1.3 Embankment Evaluation Criteria

Based on information provided by the client, the existing embankment is constructed of lean clay (CL) and fat clay (CH) with existing side slopes (both up- and downstream) of approximately 3:1 (H:V), maximum embankment height of 20 feet and top of dam elevation of 358.0 feet (MSL). The upstream base elevation of the impoundment is approximately 347.0 feet (MSL). The crest width of the embankment is approximately 25 feet. Two (2) critical sections were evaluated for this initial safety factor assessment. Section No. 1 represents the northwest corner of the West Ash embankment and Section No. 2 represents the southern berm of the embankment.

It is our understanding that the maximum storage elevation of impounded CCR ash is 355.0 feet (MSL); however, the facility is managed to maintain an ash level less than this maximum level. The downstream toe of the West Ash Pond is not adjacent to other water bodies and therefore not subject to 40 CFR §257.73(d)(1)(A)(3)(vii).

In accordance with 40 CFR §257.73(e)(1)(i) and (ii), the maximum storage pool elevation for the West Ash Pond as determined by the 25-year, 24-hour storm event is 354.81 feet (MSL). For the purposes of this evaluation, the maximum storage pool elevation of 355.0 feet (MSL) was utilized. Likewise, the maximum (or flood) surcharge loading elevation as determined by the 100-year, 24-hour event is 355.01 feet (MSL), for this evaluation a maximum surcharge loading elevation of 355.0 feet (MSL) was utilized. Storage pool elevations were determined in accordance with 40 CFR §257.82(a).

2.0 Slope Stability Analyses

2.1 General

Soil parameters used for stability analyses of the existing embankment are based on findings of previous laboratory and field testing programs. The probable failure planes were analyzed using the analytical slope stability software, SLIDE by Rocscience, Inc. Methods of evaluation used in SLIDE are considered to be limited equilibrium methods of analysis, where each individual shear plane is evaluated to determine the resulting shear stress at the point of failure. For the purposes of this evaluation the Bishop Method of analysis, which analyzes circular failure planes through the slope was utilized.

Per 40 CFR §257.73(e)(1)(i) through (iii), three (3) modeled scenarios (presented below) were utilized to evaluate the stability of the existing embankment: steady state seepage (long term) condition under maximum storage pool, steady state seepage (long term) condition under maximum surcharge pool, and steady state seepage condition with seismic loading under maximum storage pool conditions. The following minimum factors of safety (FS) and soil stress parameters were utilized in modeling. Minimum factors of safety are based on demonstration requirements provided in 40 CFR §257.73(e)(1).

Summary of Embankment Condition and Factor of Safety		
Embankment Condition	**Soil Parameters**	**Minimum Factor of Safety**
Steady State Seepage – Maximum Pool	Effective Stress	1.50
Steady State Seepage – Surcharge Pool	Effective Stress	1.40
Steady State Seepage (Seismic) – Maximum Pool	Total Stress	1.00
NOTE: Minimum factors of safety based on demonstration requirements provided in 40 CFR §257.82 (e)(1).		

For evaluation of steady state seepage (long term) conditions with seismic, peak ground acceleration for this location was obtained from the USGS National Seismic Hazard Mapping Project (http://earthquake.usgs.gov/hazards). Based on the seismic survey data, the anticipated site specific peak ground acceleration (PGA) of 0.06g (acceleration at rock sites) for two (2) percent probability of exceedance in 50 years (40 CFR Part 257, Preamble page 21384). Correcting for acceleration at soft soil sites (Seismic Site Classification D) yields an estimated PGA of 0.13g. The seismic coefficient (k) used for pseudo static analysis is determined by reducing the estimated PGA by 50% yielding a seismic coefficient of 0.065g.

2.2 Liquefaction Assessment

Liquefaction of soils occurs when horizontal shearing stresses exceed the strength of existing loose, saturated sand. This sudden loss of shear strength and subsequent soil structure is typically associated with earthquake-induced horizontal movement. Recent engineering publications[1] provide criteria to assess liquefaction potential of sands (little to no fines) and clayey soils of low plasticity (e.g. clayey sands, silts). These criteria indicate that water content of fine-grained or cohesive soils needs to be high (≥ 0.85 *Liquid Limit [LL]), a clay fine content (defined as grains smaller than 0.002 mm) of less than 10 percent (< 10%), and relatively low soil density (assessed in terms of SPT blow counts). In addition, the accepted minimum seismic threshold acceleration to cause liquefaction in loose sands is 0.10g, the anticipated site specific PGA for this site is 0.06g.

Native fine grained (or cohesive) material underlying the West Ash Pond generally consist of medium dense to very dense clayey sand (SC), clayey gravel (GC) and silty clayey sand (SC-SM) Based on these soil characteristics and that the West Ash Pond is located in a zone of low peak ground acceleration (PGA), the risk of either embankment or underlying soils liquefying are negligible [40 CFR §257.73(e)(1)(iv)].

2.3 Embankment and Foundation Stratigraphy

The models developed for this evaluation are based on the existing embankment geometry, results of field and laboratory testing and hydrologic site information provided by the client and recent field activities. Selection of critical slope sections (Section Nos. 1 and 2) was based on both height and subsurface sensitivity to loading. The following tables provide a summary of soil parameters used for these analyses. Specific soil parameters used for each model are presented in the Appendix.

Summary of Long Term, Total Stress Soil Parameters, Section No. 1:

Material Type	Unit Weight (pcf)	Consolidated-Undrained Cohesion (psf)	Consolidated-Undrained Angle of Internal Friction (degrees)
Embankment Fill	125	450	12
Lean Clay/Fat Clay (CL/CH)	125	530	13
Silty Sand/Clayey Sand (SM/SC)	125	0	28
Ash	100	0	30

NOTE: Properties used for Steady State Seepage with Seismic analysis.

Summary of Long Term, Effective Stress Soil Parameters, Section No. 1

Material Type	Unit Weight (pcf)	Consolidated-Drained Cohesion (psf)	Consolidated-Drained Angle of Internal Friction (degrees)
Embankment Fill	125	590	16
Lean Clay/Fat Clay (CL/CH)	125	320	17
Silty Sand/Clayey Sand (SM/SC)	125	430	28
Ash	100	0	30

NOTE: Properties used for Steady State Seepage analysis. Consolidated-drained conditions determined based on pore pressure measurements made during Consolidated-Undrained (CU) triaxial testing.

Summary of Long Term, Total Stress Soil Parameters, Section No. 2			
Material Type	**Unit Weight (pcf)**	**Consolidated-Undrained Cohesion (psf)**	**Consolidated-Undrained Angle of Internal Friction (degrees)**
Embankment Fill	125	450	12
Lean Clay/Fat Clay (CL/CH)	125	530	13
Clayey Sand/Silty Sand (SC/SM)	125	0	28
Lean Clay (CL)	125	260	20
Ash	100	0	30
NOTE: Properties used for Steady State Seepage with Seismic analysis.			

Summary of Long Term, Effective Stress Soil Parameters, Section No. 2			
Material Type	**Unit Weight (pcf)**	**Consolidated-Drained Cohesion (psf)**	**Consolidated-Drained Angle of Internal Friction (degrees)**
Embankment Fill	125	590	16
Lean Clay/Fat Clay (CL/CH)	125	320	17
Clayey Sand/Silty Sand (SC/SM)	125	0	28
Lean Clay (CL)	125	290	22
Ash	100	0	30
NOTE: Properties used for Steady State Seepage analysis. Consolidated-drained conditions determined based on pore pressure measurements made during Consolidated-Undrained (CU) triaxial testing.			

2.4 Seepage Analysis Parameters

The analysis of embankment seepage is based on laboratory results and estimated values for permeability for various embankment and native foundation soils. These soil parameters were utilized in the models to establish a long term steady state condition and corresponding phreatic surface in the embankment. Hydraulic conductivity test results are provided in the Appendix. Hydraulic conductivity properties utilized in the seepage analysis are provided in the below table.

Hydraulic Conductivity of Embankment Soils, Section Nos. 1 and 2	
Material Type	**Permeability (ft/sec)**
Embankment Fill	1×10^{-8}
Lean Clay/Fat Clay (CL/CH)	1×10^{-8}
Clayey Sand/Silty Sand (SC/SM)	1×10^{-5}
Lean Clay (CL)	1×10^{-8}
Ash	1×10^{-4}

2.5 Stability Analysis Results

The following tables provides the results of the stability analysis for each of the conditions cited herein, as required by 40 CFR §257.73(e)(1)(i) through (iii). The graphical representations of each analysis are included in the Appendix.

Summary of Stability Analyses – Safety Factors, Section No. 1		
Modeled Condition	**Factor of Safety**	
	Actual	**Minimum**
Steady State Seepage – Maximum Pool	2.21	1.50
Steady State Seepage – Surcharge Pool	2.21	1.40
Steady State Seepage with Seismic – Maximum Pool	1.35	1.00

Summary of Stability Analyses – Safety Factors, Section No. 2		
Modeled Condition	Factor of Safety	
	Actual	Minimum
Steady State Seepage – Maximum Pool	1.83	1.50
Steady State Seepage – Surcharge Pool	1.83	1.40
Steady State Seepage with Seismic – Maximum Pool	1.50	1.00

Based on the findings of this analysis, the evaluated embankments appear to be stable under the modeled conditions and demonstrate the minimum safety factors, as required by 40 CFR §257.73(e)(1)(i) through (iii).

3.0 Report Limitations

This report has been prepared for the exclusive use of our client for the specific application to the project discussed and has been prepared in accordance with the generally accepted geotechnical engineering practices. No warranties, either express or implied, are intended or made. The analyses contained in the report are based on the data obtained from the referenced soil borings performed within the project site. This report does not reflect variations that may occur between borings or across the site. Soil borings do not necessarily reflect strata variations that may exist at other locations within the project site.

4.0 Initial Structural Stability Assessment Certification

By means of this certification, (i) I have reviewed the requirements of 40 CFR §257.73(e)(1) – *Periodic Safety Factor Assessments*, (ii) I or my agent has visited and examined the facility, (iii) the referenced data used in this evaluation to the best of my knowledge appears correct and appropriate for use, (iv) and this Initial Safety Factor Assessment for the West Ash Pond (Pirkey Power Station) has been prepared to the best of my knowledge in accordance with §257.73(e)(1).

TERTIARY

Eocene

Etg / Es
Sparta Sand
Quartz sand, fine to medium grained, light gray to brownish gray, slightly cohesive from silt and clay matrix, massive, locally cross-bedded, interbeds of sandy clay more abundant upward, locally carbonaceous; weathers various shades of light gray, at base hard, brown, ferruginous sandstone; lower part 170± feet thick, upper part absent. Locally includes Tyler Greensand Member, Etg, quartz-glauconite greensand, grayish green, massive, locally cross-bedded; weathers dark reddish brown, abundant ironstone concretions

Ew
Weches Formation
Glauconite and quartz sand, grayish green to grayish olive green, thin bedded, locally cross-bedded to lenticular, clay interbeds light brown to moderate light gray, silty, muscovitic, thin bedded; weathers moderate to dark reddish brown, locally forms limonitic and sideritic iron ore and clay ironstone concretions; marine megafossils in southern part; 25± feet thick, range 0–70 feet

Eqc
Queen City Sand
Quartz sand, fine grained to locally medium grained, light gray to brownish gray, locally carbonaceous, and clay, gray to brown, silty, slightly lignitic, sand most abundant to west; weathers red and white mottled, ironstone concretions and ledges common; local beds of glauconite-quartz greensand, cross-bedded, weathers to ferruginous ledges and rubble; 100–400 feet thick, thins southeastward

Er
Reklaw Formation
Upper 100± feet, clay, brownish black to brownish gray, silty, muscovitic, carbonaceous, laminated, interbeds of moderate reddish-brown clay; weathers light brown, ironstone concretions common; a few marine fossils. Lower 15± feet, quartz sand, fine to very fine grained, grayish green, glauconitic, argillaceous, massive, locally cross-bedded; weathers moderate brown to dark yellowish orange with clay ironstone ledges and rubble; fossils, clay ironstone, and clay decrease northward

Ec
Carrizo Sand
Upper part, very fine sand, silt, clayey silt, silty clay, medium to dark gray, carbonaceous; weathers moderate yellowish brown to dark reddish brown, indurated ledges of dark brownish-gray ironstone common. Lower part, quartz sand, fine to medium grained, light brownish gray, weakly cohesive, massive, locally cross-bedded; weathers light gray to various shades of red. Thickness 20–100 feet

Ewi
Wilcox Group undivided
Mostly silty and sandy clay, various shades of gray, local beds of clay, lignite, silt, and quartz sand, in part carbonaceous, laminated to massive, locally cross-bedded, weathers to various shades of gray, brown, yellow, and red. Calcareous siltstone and ironstone concretions common; abundant plant fossils, a few marine fossils in southeastern part; 300–1,000 feet thick.

E
Eocene rocks undivided
Reklaw Formation, Carrizo Sand, Wilcox Group, and Midway Group on Brooks dome, not separately shown

Ewp
Wills Point Formation
Clay, medium bluish gray, greenish gray, grayish green, brownish gray, silt increases upward, laminated to locally massive, glauconitic near base, rough calcareous siltstone concretions common in upper part, locally lignitic in upper part, thin bed of [illegible] limestone near middle; weathers medium gray to yellowish gray; fossiliferous; 500± feet thick

Ek
Kincaid Formation
Clay, medium gray to dark gray, greenish gray, brownish gray, glauconitic, calcareous, selenitic, locally silty or sandy, locally phosphatic near base, thin beds of limestone in upper part, gray, hard, detrital; weathers medium gray; fossiliferous; 180± feet thick

CRETACEOUS

Upper Cretaceous

Kk
Kemp Clay
Clay, dark gray to bluish gray, calcareous, silty, glauconitic, calcareous concretions common; weathers dark greenish gray and black; upper part only crops out

Ku
Upper Cretaceous rocks undivided
Navarro Group, Taylor Group, and Austin Chalk on Brooks dome not separately shown

2.8 – West Bottom Ash Pond Hazard Potential Classification Assessment, July 2021

Southwestern Electric Power Company
Pirkey Power Station
West Bottom Ash Pond

Hazard Potential Classification Assessment

AEP has performed an evaluation to classify the above CCR Surface Impoundment in accordance with FEMA's Hazard Potential Classification System for Dams. These guidelines evaluate the consequences of a potential failure not the likelihood of a failure. Guidelines that were developed and utilized are included below.

Hazard Potential Classification Systems (from FEMA 333, April 2004)

1. **Low Hazard Potential**
   Dams assigned the low hazard potential classification are those where failure or mis-operation results in no probable loss of human life and low economic and/or environmental losses. Losses are principally limited to the owner's property.
2. **Significant Hazard Potential**
   Dams assigned the significant hazard potential classification are those dams where failure or mis-operation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in areas with population and significant infrastructure.
3. **High Hazard Potential**
   Dams assigned the high hazard potential classification are those where failure or mis-operation will probably cause loss of human life.

The AEP H.W. Pirkey Power Station is located at 2400 FM 3251, Hallsville, TX 75650. The plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas.

The West Bottom Ash Pond is located at the north end of the Plant and approximately 3,000 feet northwest of Brandy Branch Reservoir. Loss of human life is not probable in the event of a catastrophic failure of the embankment and a failure of the embankment is expected to have a low economic and environmental impact. The US EPA CCR Impoundment Assessment Report has listed this ash pond as Low Hazard.

There has been no changes in classification by the State Dam Safety nor has there been any other physical changes that would warrant a change in the classification.

Based on the FEMA Hazard Potential Classification Systems for Dams and on the above discussion, Pirkey West Bottom Ash Pond Dam is classified as a **Low Hazard Potential Dam**.

Professional Engineer's Certification:

I certify that this Hazard Potential Classification Assessment is in accordance with the requirements of section 30 TAC 352.731.

Table of CONTENTS

1.0 OBJECTIVE

This report was prepared by AEP- Geotechnical Engineering Services (GES) section to fulfill requirements of 30 TAC 352.731 (40 CFR 257.73(e)) for the safety factor assessment of CCR surface impoundments. This is the first periodic 5-year review of the safety factor assessment.

2.0 DESCRIPTION OF THE CCR UNIT

The Henry W. Pirkey Power Station is located at 2400 FM 3251 and south of Hallsville, Texas.
It is owned and operated by Southwest Electric Power Company (SWEPCO). The facility operates two surface impoundments for storing CCR materials called the East Bottom Ash Pond (East BAP) and the West Bottom Ash Pond (West BAP).

The West BAP is located northwest of the main plant and shares its eastern border with the western border of the East BAP. The West BAP receives sluiced bottom ash and has a surface area of 30 acres and a storage capacity of 188 acre-feet. The maximum embankment height is 25 feet. Design documents indicate that the main upstream embankment slopes are 3 feet horizontal to 1 foot vertical (3:1 H:V); while the main downstream slopes are 2.5:1 H:V.

3.0 SAFETY FACTOR ASSESSMENT 257.73(e)

The periodic 5-year review was conducted to evaluate if any physical changes have been made to the earthen dike and/or operating changes that could impact the loading on the structure. The assumptions, material properties and operating pools defined in the initial assessment were reviewed. The review concluded that there have been no changes that would impact the stability analyses that were previously conducted. Therefore, the previous report and analyses are still applicable to the current conditions of the facility. The results indicate that the calculated factors of safety meet or exceed the minimum values defined in Section 257.73(e).

Appendix

1.0 Introduction and Embankment Information

1.1 Introduction

The following report and evaluation provides the Initial Safety Factor Assessment of the West Ash Pond, an existing CCR impoundment (as defined by 40 CFR §257.2) located at the Pirkey Power Station near Hallsville, Texas. In accordance with 40 CFR §257.73(e)(1)(i) through (iv) this initial assessment provides field and laboratory data, model outputs (detailing multiple stability conditions) and summary of safety factors for the West Ash Pond. In accordance with 40 CFR §257.73(e)(2) this report provides the Initial Safety Factor Assessment certification for the West Ash Pond.

1.2 Referenced Information and Data

Soils data, comprised of field and laboratory testing, utilized in the preparation of this assessment were completed by ETTL Engineers and Consultants, Inc. and documented in the report *Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas* dated October 12, 2010. Based on a review of the provided field and laboratory data, it appears to be accurate and appropriate for use in the initial structural stability assessment of the West Ash Pond [40 CFR §257.73(e)(1)]. Furthermore, based on a recent site visit (October 2015), no modifications or elevation alterations have been made to the embankment since the referenced investigation. No additional field or laboratory activities were conducted. Soil data utilized in this evaluation is provided in the Appendix of this report.

To supplement existing data collected in the above reference report, an additional eight (8) Cone Penetrometer Test (CPT) soundings were advanced both along the crest and southern toe of the West Ash Pond. Sounding depths ranged between approximately 14 feet and 40 feet before encountering refusal. The data collected generally supports the findings from the 2010 study and confirms that embankment and foundation soils are relatively consistent. The location of and data from these CPT soundings are provided in the Appendix of this report.

The impoundment pool elevation data cited herein were provided in a separate hydrology and hydraulic (H&H) analysis report completed by Akron Consulting, LLC titled *Hydrology & Hydraulic Report, East & West Ash Ponds, H.W. Pirkey Power Plant – Hallsville, Texas,* dated December 15, 2015 (not included herein). The referenced report generally meets the demonstration requirements of 40 CFR §257.82(a).

Embankment profile dimensions and elevations were determined by using existing information provided by the client or representatives of the client. This information is also included in the Appendix of this report.

1.3 Embankment Evaluation Criteria

Based on information provided by the client, the existing embankment is constructed of lean clay (CL) and fat clay (CH) with existing side slopes (both up- and downstream) of approximately 3:1 (H:V), maximum embankment height of 20 feet and top of dam elevation of 358.0 feet (MSL). The upstream base elevation of the impoundment is approximately 347.0 feet (MSL). The crest width of the embankment is approximately 25 feet. Two (2) critical sections were evaluated for this initial safety factor assessment. Section No. 1 represents the northwest corner of the West Ash embankment and Section No. 2 represents the southern berm of the embankment.

It is our understanding that the maximum storage elevation of impounded CCR ash is 355.0 feet (MSL); however, the facility is managed to maintain an ash level less than this maximum level. The downstream toe of the West Ash Pond is not adjacent to other water bodies and therefore not subject to 40 CFR §257.73(d)(1)(A)(3)(vii).

In accordance with 40 CFR §257.73(e)(1)(i) and (ii), the maximum storage pool elevation for the West Ash Pond as determined by the 25-year, 24-hour storm event is 354.81 feet (MSL). For the purposes of this evaluation, the maximum storage pool elevation of 355.0 feet (MSL) was utilized. Likewise, the maximum (or flood) surcharge loading elevation as determined by the 100-year, 24-hour event is 355.01 feet (MSL), for this evaluation a maximum surcharge loading elevation of 355.0 feet (MSL) was utilized. Storage pool elevations were determined in accordance with 40 CFR §257.82(a).

2.0 Slope Stability Analyses

2.1 General

Soil parameters used for stability analyses of the existing embankment are based on findings of previous laboratory and field testing programs. The probable failure planes were analyzed using the analytical slope stability software, SLIDE by Rocscience, Inc. Methods of evaluation used in SLIDE are considered to be limited equilibrium methods of analysis, where each individual shear plane is evaluated to determine the resulting shear stress at the point of failure. For the purposes of this evaluation the Bishop Method of analysis, which analyzes circular failure planes through the slope was utilized.

Per 40 CFR §257.73(e)(1)(i) through (iii), three (3) modeled scenarios (presented below) were utilized to evaluate the stability of the existing embankment: steady state seepage (long term) condition under maximum storage pool, steady state seepage (long term) condition under maximum surcharge pool, and steady state seepage condition with seismic loading under maximum storage pool conditions. The following minimum factors of safety (FS) and soil stress parameters were utilized in modeling. Minimum factors of safety are based on demonstration requirements provided in 40 CFR §257.73(e)(1).

Summary of Embankment Condition and Factor of Safety		
Embankment Condition	**Soil Parameters**	**Minimum Factor of Safety**
Steady State Seepage – Maximum Pool	Effective Stress	1.50
Steady State Seepage – Surcharge Pool	Effective Stress	1.40
Steady State Seepage (Seismic) – Maximum Pool	Total Stress	1.00
NOTE: Minimum factors of safety based on demonstration requirements provided in 40 CFR §257.82 (e)(1).		

For evaluation of steady state seepage (long term) conditions with seismic, peak ground acceleration for this location was obtained from the USGS National Seismic Hazard Mapping Project (http://earthquake.usgs.gov/hazards). Based on the seismic survey data, the anticipated site specific peak ground acceleration (PGA) of 0.06g (acceleration at rock sites) for two (2) percent probability of exceedance in 50 years (40 CFR Part 257, Preamble page 21384). Correcting for acceleration at soft soil sites (Seismic Site Classification D) yields an estimated PGA of 0.13g. The seismic coefficient (k) used for pseudo static analysis is determined by reducing the estimated PGA by 50% yielding a seismic coefficient of 0.065g.

2.2 Liquefaction Assessment

Liquefaction of soils occurs when horizontal shearing stresses exceed the strength of existing loose, saturated sand. This sudden loss of shear strength and subsequent soil structure is typically associated with earthquake-induced horizontal movement. Recent engineering publications[1] provide criteria to assess liquefaction potential of sands (little to no fines) and clayey soils of low plasticity (e.g. clayey sands, silts). These criteria indicate that water content of fine-grained or cohesive soils needs to be high (≥ 0.85 *Liquid Limit [LL]), a clay fine content (defined as grains smaller than 0.002 mm) of less than 10 percent (< 10%), and relatively low soil density (assessed in terms of SPT blow counts). In addition, the accepted minimum seismic threshold acceleration to cause liquefaction in loose sands is 0.10g, the anticipated site specific PGA for this site is 0.06g.

Native fine grained (or cohesive) material underlying the West Ash Pond generally consist of medium dense to very dense clayey sand (SC), clayey gravel (GC) and silty clayey sand (SC-SM) Based on these soil characteristics and that the West Ash Pond is located in a zone of low peak ground acceleration (PGA), the risk of either embankment or underlying soils liquefying are negligible [40 CFR §257.73(e)(1)(iv)].

---

[1] Seed, R.B., et al, Recent Advances in Soil Liquefaction Engineering: A Unified and Consistent Framework, 26th Annual ASCE Los Angeles Spring Seminar, April 2003

2.3 Embankment and Foundation Stratigraphy

The models developed for this evaluation are based on the existing embankment geometry, results of field and laboratory testing and hydrologic site information provided by the client and recent field activities. Selection of critical slope sections (Section Nos. 1 and 2) was based on both height and subsurface sensitivity to loading. The following tables provide a summary of soil parameters used for these analyses. Specific soil parameters used for each model are presented in the Appendix.

Summary of Long Term, Total Stress Soil Parameters, Section No. 1:

Material Type	Unit Weight (pcf)	Consolidated-Undrained Cohesion (psf)	Consolidated-Undrained Angle of Internal Friction (degrees)
Embankment Fill	125	450	12
Lean Clay/Fat Clay (CL/CH)	125	530	13
Silty Sand/Clayey Sand (SM/SC)	125	0	28
Ash	100	0	30

NOTE: Properties used for Steady State Seepage with Seismic analysis.

Summary of Long Term, Effective Stress Soil Parameters, Section No. 1

Material Type	Unit Weight (pcf)	Consolidated-Drained Cohesion (psf)	Consolidated-Drained Angle of Internal Friction (degrees)
Embankment Fill	125	590	16
Lean Clay/Fat Clay (CL/CH)	125	320	17
Silty Sand/Clayey Sand (SM/SC)	125	430	28
Ash	100	0	30

NOTE: Properties used for Steady State Seepage analysis. Consolidated-drained conditions determined based on pore pressure measurements made during Consolidated-Undrained (CU) triaxial testing.

Summary of Long Term, Total Stress Soil Parameters, Section No. 2			
Material Type	**Unit Weight (pcf)**	**Consolidated-Undrained Cohesion (psf)**	**Consolidated-Undrained Angle of Internal Friction (degrees)**
Embankment Fill	125	450	12
Lean Clay/Fat Clay (CL/CH)	125	530	13
Clayey Sand/Silty Sand (SC/SM)	125	0	28
Lean Clay (CL)	125	260	20
Ash	100	0	30
NOTE: Properties used for Steady State Seepage with Seismic analysis.			

Summary of Long Term, Effective Stress Soil Parameters, Section No. 2			
Material Type	**Unit Weight (pcf)**	**Consolidated-Drained Cohesion (psf)**	**Consolidated-Drained Angle of Internal Friction (degrees)**
Embankment Fill	125	590	16
Lean Clay/Fat Clay (CL/CH)	125	320	17
Clayey Sand/Silty Sand (SC/SM)	125	0	28
Lean Clay (CL)	125	290	22
Ash	100	0	30
NOTE: Properties used for Steady State Seepage analysis. Consolidated-drained conditions determined based on pore pressure measurements made during Consolidated-Undrained (CU) triaxial testing.			

2.4 Seepage Analysis Parameters

The analysis of embankment seepage is based on laboratory results and estimated values for permeability for various embankment and native foundation soils. These soil parameters were utilized in the models to establish a long term steady state condition and corresponding phreatic surface in the embankment. Hydraulic conductivity test results are provided in the Appendix. Hydraulic conductivity properties utilized in the seepage analysis are provided in the below table.

Hydraulic Conductivity of Embankment Soils, Section Nos. 1 and 2	
Material Type	**Permeability (ft/sec)**
Embankment Fill	1×10^{-8}
Lean Clay/Fat Clay (CL/CH)	1×10^{-8}
Clayey Sand/Silty Sand (SC/SM)	1×10^{-5}
Lean Clay (CL)	1×10^{-8}
Ash	1×10^{-4}

2.5 Stability Analysis Results

The following tables provides the results of the stability analysis for each of the conditions cited herein, as required by 40 CFR §257.73(e)(1)(i) through (iii). The graphical representations of each analysis are included in the Appendix.

Summary of Stability Analyses – Safety Factors, Section No. 1		
Modeled Condition	**Factor of Safety**	
	Actual	**Minimum**
Steady State Seepage – Maximum Pool	2.21	1.50
Steady State Seepage – Surcharge Pool	2.21	1.40
Steady State Seepage with Seismic – Maximum Pool	1.35	1.00

Summary of Stability Analyses – Safety Factors, Section No. 2		
Modeled Condition	**Factor of Safety**	
	Actual	**Minimum**
Steady State Seepage – Maximum Pool	1.83	1.50
Steady State Seepage – Surcharge Pool	1.83	1.40
Steady State Seepage with Seismic – Maximum Pool	1.50	1.00

Based on the findings of this analysis, the evaluated embankments appear to be stable under the modeled conditions and demonstrate the minimum safety factors, as required by 40 CFR §257.73(e)(1)(i) through (iii).

3.0 Report Limitations

This report has been prepared for the exclusive use of our client for the specific application to the project discussed and has been prepared in accordance with the generally accepted geotechnical engineering practices. No warranties, either express or implied, are intended or made. The analyses contained in the report are based on the data obtained from the referenced soil borings performed within the project site. This report does not reflect variations that may occur between borings or across the site. Soil borings do not necessarily reflect strata variations that may exist at other locations within the project site.

4.0 Initial Structural Stability Assessment Certification

By means of this certification, (i) I have reviewed the requirements of 40 CFR §257.73(e)(1) – *Periodic Safety Factor Assessments*, (ii) I or my agent has visited and examined the facility, (iii) the referenced data used in this evaluation to the best of my knowledge appears correct and appropriate for use, (iv) and this Initial Safety Factor Assessment for the West Ash Pond (Pirkey Power Station) has been prepared to the best of my knowledge in accordance with §257.73(e)(1).

EXPLANATION

SEDIMENTARY ROCKS

QUATERNARY

Pleistocene Recent

Qal

Alluvium

Flood-plain deposits

Qt

Fluviatile terrace deposits undivided

TERTIARY

Eocene

Etg / Es

Sparta Sand

Quartz sand, fine to medium grained, light gray to brownish gray, slightly cohesive from silt and clay matrix, massive, locally cross-bedded, interbeds of sandy clay more abundant upward, locally carbonaceous; weathers various shades of light gray, at base hard, brown, ferruginous sandstone; lower part 170± feet thick, upper part absent. Locally includes Tyler Greensand Member, Etg, quartz-glauconite greensand, grayish green, massive, locally cross-bedded; weathers dark reddish brown, abundant ironstone concretions

Ew

Weches Formation

Glauconite and quartz sand, grayish green to grayish olive green, thin bedded, locally cross-bedded to lenticular, clay interbeds light brown to moderate light gray, silty, muscovitic, thin bedded; weathers moderate to dark reddish brown, locally forms limonitic and sideritic iron ore and clay ironstone concretions; marine megafossils in southern part; 25± feet thick, range 0–70 feet

Eqc

Queen City Sand

Quartz sand, fine grained to locally medium grained, light gray to brownish gray, locally carbonaceous, and clay, gray to brown, silty, slightly lignitic, sand most abundant to west; weathers red and white mottled, ironstone concretions and ledges common; local beds of glauconite-quartz greensand, cross-bedded, weathers to ferruginous ledges and rubble; 100–400 feet thick, thins southeastward

Er

Reklaw Formation

Upper 100± feet, clay, brownish black to brownish gray, silty, muscovitic, carbonaceous, laminated, interbeds of moderate reddish-brown clay; weathers light brown, ironstone concretions common; a few marine fossils. Lower 15± feet, quartz sand, fine to very fine grained, grayish green, glauconitic, argillaceous, massive, locally cross-bedded; weathers moderate brown to dark yellowish orange with clay ironstone ledges and rubble; fossils, clay ironstone, and clay decrease northward

Ec

Carrizo Sand

Upper part, very fine sand, silt, clayey silt, silty clay, medium to dark gray, carbonaceous; weathers moderate yellowish brown to dark reddish brown, indurated ledges of dark brownish-gray ironstone common. Lower part, quartz sand, fine to medium grained, light brownish gray, weakly cohesive, massive, locally cross-bedded; weathers light gray to various shades of red. Thickness 20–100 feet

Ewi

Wilcox Group undivided

Mostly silty and sandy clay, various shades of gray, local beds of clay, lignite, silt, and quartz sand, in part carbonaceous, laminated to massive, locally cross-bedded, weathers to various shades of gray, brown, yellow, and red. Calcareous siltstone and ironstone concretions common; abundant plant fossils, a few marine fossils in southeastern part; 500–1,000 feet thick.

E

Eocene rocks undivided

Reklaw Formation, Carrizo Sand, Wilcox Group, and Midway Group on Brooks dome not separately shown

Ewp

Wills Point Formation

Clay, medium bluish gray, greenish gray, grayish green, brownish gray, silt increases upward, laminated to locally massive, glauconitic near base, rough calcareous siltstone concretions common in upper part, locally lignitic in upper part, thin bed of coquina limestone near middle; weathers medium gray to yellowish gray; fossiliferous; 500± feet thick

Ek

Kincaid Formation

Clay, medium gray to dark gray, greenish gray, brownish gray, glauconitic, calcareous, selenitic, locally silty or sandy, locally phosphatic near base, thin beds of limestone in upper part, gray, hard, detrital; weathers medium gray; fossiliferous; 150± feet thick

CRETACEOUS

Upper Cretaceous

Kke

Kemp Clay

Clay, dark gray to bluish gray, calcareous, silty, glauconitic, calcareous concretions common; weathers dark greenish gray and black; upper part only crops out

Ku

Upper Cretaceous rocks undivided

Navarro Group, Taylor Group, and Austin Chalk on Brooks dome not separately shown

Date

1.0 INTRODUCTION

This CCR Fugitive Dust Control Plan (Plan) has been prepared pursuant to the air criteria of 40 CFR part 257.80 (see Appendix A). The Plan has been prepared in accordance with the air criteria and following good engineering practices to include measures that will effectively minimize CCR from becoming airborne at the facility. The Plan and subsequent amendments will be placed in the operating record and retained in the office of the Pirkey Plant Environmental Coordinator (PEC). The Plan and subsequent amendments will also be placed on Pirkey Plant's publicly accessible internet website titled "CCR Rule Compliance Data and Information." The plan will be amended whenever there is a change in conditions that would substantially affect the written plan in effect, such as the construction and operation of a new CCR unit. Where appropriate, the Plan incorporates fugitive dust control requirements as contained in the TCEQ air permits issued for the plant.

There are two CCR surface impoundments, one CCR pile and one CCR landfill located at Pirkey Plant that are subject to the Plan. The surface impoundments are the east and west bottom ash ponds; the CCR pile, called the FGD Stackout Area, is the area where the scrubber sludge and flyash is stacked out before it is trucked to the onsite landfill; and the Residual Waste Landfill (Landfill) receives both scrubber sludge/flyash mixture and bottom ash which is periodically removed from the bottom ash ponds. The Plan addresses these CCR units and the associated unpaved roadways.

2.0 FACILITY DESCRIPTION AND CONTACT INFORMATION

2.1 Facility Information

Facility Information
Name of Facility: H.W. Pirkey Power Plant
Street: 2400 FM 3251
City, State, ZIP Code: Hallsville, TX 75650
County: Harrison
Latitude: 32º 27'43'' N Longitude: 94º 29' 07'' W

2.2 Contact Information

Facility Operator:
Name: Southwestern Electric Power Company
Attention: Joel Endsley - Plant Manager
Address: 2400 FM 3251
City, State, Zip Code: Hallsville, TX 75650

Facility Owner:
Name: Southwestern Electric Power Company
Northwest Texas Electric Cooperative, Inc.
Oklahoma Municipal Power Authority
Attention: William Hildeson – Environmental Guru
Address: Environmental Services – Floor 17
City, State, Zip Code: 1 Riverside Plaza Columbus OH 43215

Plan Contact:
Name: Samantha McDonald – Pirkey Plant Environmental Coordinator
Address: 2400 FM 3251
City, State, Zip Code: Hallsville, TX 75650
Telephone number: 903-927-5853
Email address: ssmcdonald@aep.com

2.3 Activities at the Facility

The Pirkey Power Plant is located in Northeast Texas. The H. W. Pirkey plant made history for AEP SWEPCO as the first plant built by the company to use lignite as its primary fuel source. Compared to other forms of coal, lignite contains a smaller amount of fixed carbon and has a lower heating value, but is plentiful and close to the surface where it is mined. Sabine Mining Company, a subsidiary of North American Coal Corporation, provides the lignite burned at Pirkey. Pirkey, a 675 MW plant, is co-owned by AEP SWEPCO, Northeast Texas Electric Cooperative and Oklahoma Municipal Power Authority. AEP-SWEPCO manages and operates the plant on behalf of its co-owners.

Pirkey is equipped with a flue gas desulfurization (FGD) system or scrubber that uses a limestone-water slurry to remove up to 95% of the SO_2 that results from lignite combustion. The FGD sludge from this process is combined with the flyash (that isn’t marketed to outside vendors) and transported by truck to the plant’s onsite Landfill.

Bottom ash is produced by the unit and is wet sluiced to the BAP during unit operations. The bottom ash is routinely reclaimed from the pond, loaded into trucks and transported to the Landfill for disposal.

The fly ash handling system is enclosed. Electrostatic Precipitators (ESP) remove more than 99% of all the flyash particles produced by coal combustion. In the precipitators, fly ash from burning coal passes through electrically-charged plates, which pull the ash particles out of the exhaust gas stream. The ash can be marketed for use in land reclamation, in concrete and lightweight aggregate and in the production of roofing and other products.

2.4 Site Maps

A Pirkey Pant property boundary aerial view map is included in Appendix B. Appendix C contains an aerial view that includes the bottom ash ponds, FGD Stackout area, and the Landfill.

3.0 FUGITIVE DUST CONTROL SELECTION

3.1 Paved and Unpaved Roadways

3.1.1 Overview

Trucks are used to transport CCR to the Landfill from the FGD Stackout Area and Bottom Ash Ponds.

3.1.2 Landfill and Plant Roadways

The primary appropriate and applicable fugitive dust control measures for roadways are watering and speed controls. Water trucks are used as needed based on routine evaluations and other observations to minimize or eliminate fugitive dust. Chemical suppressants or stabilizers may also be used on unpaved roadways depending on specific site conditions. Posted speed limits are 15 mph for paved and unpaved roads. Earth or other materials that may be deposited onto unpaved roadways from trucks will be promptly removed to minimize fugitive emissions. Implementation of control measures will not be necessary for roadways that are covered with snow and/or ice or if sufficient precipitation occurs to minimize or eliminate fugitive dust. Implementation of any control measures may be suspended if unsafe or hazardous driving conditions would be created by its use.

3.2 CCR Stackout Area and Landfill

3.2.1 Overview

The CCR Stackout Area is a CCR pile where FGD/Flyash Sludge is stacked out or placed into the CCR Stackout Area using a conveyor system. The CCR material is then loaded and trucked to the Landfill.

The Landfill receives FGD/Flyash Sludge and bottom ash from the Pirkey Plant. Both materials contain moisture (conditioned) but water is added at the landfill as necessary to minimize fugitive dust emissions.

The Landfill activities are subject to the plant's TCEQ Title V Operating Permit (O31). The permit also includes visible particulate emissions limits as well as monitoring, recordkeeping and reporting requirements. [**Note**: "conditioned" CCR means the material has sufficient moisture content to prevent wind dispersal but will not result in free liquids]

3.2.2 Loading, Unloading and Placement

The FGD/Flyash Sludge typically contains moisture, but there may be fugitive emissions from the pile at the FGD Stackout area or during truck loading activities. A review of potential control measures concluded that the applicable and appropriate options consist of wetting the sludge before loading and minimizing the drop height when the sludge is being placed in the trucks.

FGD/Flyash Sludge is unloaded from trucks in the active fill area of an open Landfill cell where a bulldozer or similar equipment will spread and compact the materials. A roller may also be used for compaction. Bottom ash is unloaded from trucks into a storage pile for use in construction or disposal within the Landfill. The fugitive dust control measures for truck unloading includes maintaining moisture in the material and taking precautionary measures (minimize drop height). The measures for spreading and compacting include maintaining vehicle speed and watering materials.

3.2.3 Wind Erosion

Wind erosion at the CCR Stackout Area is mitigated by maintaining the moisture content of the Sludge at a level which minimizes dusting. The radial stacker in the Stack out Area is equipped with a sprinkler system and utilized to minimize fugitive dust emissions.

Generally, landfill disposal areas can be classified as closed or open. Closed areas have received final cover and vegetation has been established. Open areas contain both the active fill area and areas that have been compacted but not yet received final cover. The open area fugitive dust control measures include: precautionary measures such as minimizing the amount of open area and pile height; compacting material as it is unloaded and watering. The bottom ash storage pile fugitive dust emissions are minimized by watering, and pile height control.

3.3 Bottom Ash Ponds

Pirkey Plant bottom ash is produced by the unit and is wet sluiced to the East or West BAP during unit operations. The bottom ash is routinely reclaimed from the ponds, loaded into trucks and transported to the Landfill for storage. While the bottom ash typically remains wet, depending on the amount of moisture remaining in the ash and seasonal conditions, there may be fugitive emissions from the pile or truck loading activities. A review of potential control measures concluded that the applicable and appropriate options consist of: watering and minimizing drop height. Water is applied to the pile to minimize fugitive emissions as needed.

4.0 PLAN ASSESSMENT

The Plan will be periodically assessed to verify its effectiveness, and if necessary, amended in accordance with Section 7.0 below. The Landfill, BAPs and associated unpaved roadways are routinely evaluated to determine if the control measures for each CCR unit as described above are being implemented as necessary to minimize or eliminate fugitive emissions. The PEC will include the control measure evaluations during the annual assessment of the Plan and determine if additional or modified measures are warranted. No evaluations are necessary if the surface is covered with snow and/or ice or if precipitation has occurred that is sufficient to minimize or eliminate fugitive emissions. Implementation of any control measure may be suspended if unsafe or hazardous driving conditions would be created by its use.

5.0 CITIZEN COMPLAINT LOG

5.1 Plant Contacts

Generally, complaints made to the plant are by telephone and received by the PEC (Plan Contact). In the case of holiday, weekends, or other times when the PEC may not be onsite, the plant guard houses or plant general phone number may receive complaint information by telephone that is provided to the PEC at the earliest convenience. Complaints may also be made to TCEQ who in turn will contact the PEC.

5.2 Follow-up

All complaints will be entered into a log by the PEC with details noted such as the nature of the complaint, date, time, and other relevant details. All complaints will be followed up which may include: checking plant operations at the time of the event, reviewing inspection records, discussing with other plant personnel, reviewing weather data, collecting samples and contacting the person making the complaint to obtain additional information.

5.3 Corrective Action and Documentation

Corrective actions will be taken as needed and documented. If it is determined that the Plan needs to be amended as a result of the corrective actions, it will be amended in accordance with the Plan. If necessary, the PEC will follow-up with the complainant and/or TCEQ to explain the findings of the complaint investigation, corrective actions or sampling results. Citizen complaints will be recorded in the Annual Report.

6.0 ANNUAL REPORT

The Annual CCR fugitive dust control report (Annual Report) will be prepared which includes the following components: description of actions taken to control CCR fugitive dust; a record of all citizen complaints; and a summary of any corrective measures taken. The initial Annual Report will be completed no later than 14 months after placing the initial CCR fugitive dust control plan in the facility's operating record. The deadline for completing subsequent reports is one year after the date of completing the previous report. The Annual Report will be deemed complete when the plan has been placed in the facility's operating record as described in Section 8.0.

7.0 PLAN AMENDMENTS

This Plan is a "living" document and will be amended, as necessary, whenever there is a change in condition that would substantially affect the written plan in effect. The Plan will be amended in the case of construction and operation of a new CCR unit. Amendments made to the Plan will be documented in Appendix D. The amended Plan will be placed into the facility's operating record as described in Section 8.0.

8.0 RECORDKEEPING, NOTIFICATION and INTERNET REQUIREMENTS

8.1 Recordkeeping

The Plan and files of all related information will be maintained in a written operating record at the facility for at least five years following the date of each occurrence, measurement, maintenance, corrective action, report, record or study. Files may be maintained on a computer or storage system accessible by a computer. One recordkeeping system may be used for the BAPs, Stackout Area, and Landfill if the system identifies each file by the name of each unit (i.e. BAPs, Stackout Area or Landfill). The Plan (and any subsequent amendment of the plan) and the Annual Report will be kept in the facility's operating record as they become available. Only the most recent Plan must be maintained in the record.
[§ 257.105]

8.2 Notification

TCEQ will be notified within 30 days of when the Plan (or any subsequent amended Plan) or the Annual Report is placed in the operating record and on the publicly available internet site. This notification will be made before the close of business on the day the notification is required to be completed. “Before the close of business day” means the notification must be postmarked or sent by e-mail. If the notification deadline falls on a weekend or federal holiday, the notification is automatically extended to the next business day. [§ 257.106]

8.3 Internet Site Requirements

The most recent Plan and Annual Report will be placed on the facility’s CCR website titled “CCR Rule Compliance Data and Information” within 30 days of placing them in the operating record. [§ 257.107]

Appendix A

40 CFR Part 257.80 Operating Criteria

§ 257.80 Air criteria.

(a) The owner or operator of a CCR landfill, CCR surface impoundment, or any lateral expansion of a CCR unit must adopt measures that will effectively minimize CCR from becoming airborne at the facility, including CCR fugitive dust originating from CCR units, roads, and other CCR management and material handling activities.

(b) CCR fugitive dust control plan.

The owner or operator of the CCR unit must prepare and operate in accordance with a CCR fugitive dust control plan as specified in paragraphs (b)(1) through (7) of this section. This requirement applies in addition to, not in place of, any applicable standards under the Occupational Safety and Health Act.

(1) The CCR fugitive dust control plan must identify and describe the CCR fugitive dust control measures the owner or operator will use to minimize CCR from becoming airborne at the facility. The owner or operator must select, and include in the CCR fugitive dust control plan, the CCR fugitive dust control measures that are most appropriate for site conditions, along with an explanation of how the measures selected are applicable and appropriate for site conditions. Examples of control measures that may be appropriate include: Locating CCR inside an enclosure or partial enclosure; operating a water spray or fogging system; reducing fall distances at material drop points; using wind barriers, compaction, or vegetative covers; establishing and enforcing reduced vehicle speed limits; paving and sweeping roads; covering trucks transporting CCR; reducing or halting operations during high wind events; or applying a daily cover.

(2) If the owner or operator operates a CCR landfill or any lateral expansion of a CCR landfill, the CCR fugitive dust control plan must include procedures to emplace CCR as conditioned CCR. Conditioned CCR means wetting CCR with water to a moisture content that will prevent wind dispersal, but will not result in free liquids. In lieu of water, CCR conditioning may be accomplished with an appropriate chemical dust suppression agent.

(3) The CCR fugitive dust control plan must include procedures to log citizen complaints received by the owner or operator involving CCR fugitive dust events at the facility.

(4) The CCR fugitive dust control plan must include a description of the procedures the owner or operator will follow to periodically assess the effectiveness of the control plan.

(5) The owner or operator of a CCR unit must prepare an initial CCR fugitive dust control plan for the facility no later than October 19, 2015, or by initial receipt of CCR in any CCR unit at the facility if the owner or operator becomes subject to this subpart after October 19, 2015. The owner or operator has completed the initial CCR fugitive dust control plan when the plan has been placed in the facility’s operating record as required by § 257.105(g)(1).

(6) Amendment of the plan. The owner or operator of a CCR unit subject to the requirements of this section may amend the written CCR fugitive dust control plan at any time provided the revised plan is placed in the facility's operating record as required by § 257.105(g)(1). The owner or operator must amend the written plan whenever there is a change in conditions that would substantially affect the written plan in effect, such as the construction and operation of a new CCR unit.

(7) The owner or operator must obtain a certification from a qualified professional engineer that the initial CCR fugitive dust control plan, or any subsequent amendment of it, meets the requirements of this section.

(c) Annual CCR fugitive dust control report. The owner or operator of a CCR unit must prepare an annual CCR fugitive dust control report that includes a description of the actions taken by the owner or operator to control CCR fugitive dust, a record of all citizen complaints, and a summary of any corrective measures taken. The initial annual report must be completed no later than 14 months after placing the initial CCR fugitive dust control plan in the facility's operating record. The deadline for completing a subsequent report is one year after the date of completing the previous report. For purposes of this paragraph (c), the owner or operator has completed the annual CCR fugitive dust control report when the plan has been placed in the facility's operating record as required by § 257.105(g)(2).

(d) The owner or operator of the CCR unit must comply with the recordkeeping requirements specified in § 257.105(g), the notification requirements specified in § 257.106(g), and the internet requirements specified in § 257.107(g).

1.0 INTRODUCTION

This Annual CCR Fugitive Dust Control Report (Annual Report) has been prepared pursuant to the air criteria of 40 CFR Part 257.80. The Annual Report summarizes activities described in the CCR fugitive dust control plan (Plan) and includes the following components: description of actions taken to control CCR fugitive dust; a record of all citizen complaints; and a summary of any corrective measures taken.

The initial H.W. Pirkey Power Plant CCR fugitive dust control plan was placed into the operating record on October 14, 2015. This Annual Report addresses the period from September 20, 2020 to September 21, 2021. The Annual Report is deemed complete when it is placed in the facility's operating record as described in Section 6.0. The deadline for completing subsequent Annual Reports is one year after the date of completing the previous report.

The Annual Report will be placed in the operating record and retained in the office of the Pirkey Plant Environmental Coordinator (PEC). The Plan will also be placed on Pirkey Plant's publicly accessible internet website titled "CCR Rule Compliance Data and Information" as described in Section 6.0.

2.0 FACILITY DESCRIPTION AND CONTACT INFORMATION

2.1 Facility Information

General Information:

Name of Facility: Southwestern Electric Power Company – H.W. Pirkey Power Plant
Street: 2400 FM 3251
City, State, Zip Code: Hallsville, TX 75650
County: Harrison
Latitude: 32º 27'43'' N Longitude: 94º 29' 07'' W

2.2 Contact Information

2.3 Facility Description

The Pirkey Power Plant is located in Northeast Texas. The H.W. Power Plant made history for AEP-SWEPCO as the first plant built by the company to use lignite as its primary fuel source. Compared to other forms of coal, lignite contains a smaller amount of fixed carbon and has a lower heating value, but is plentiful and close to the surface where it is mined. Sabine Mining Company, a subsidiary of North American Coal Corporation, provides the lignite burned at Pirkey. Pirkey, a 675 MW plant, is co-owned by AEP SWEPCO, Northeast Texas Electric Coop. and Oklahoma Municipal Power Authority. AEP-SWEPCO manages and operates the plant on behalf of its co-owners.

See the Plan for a further description of plant activities and fugitive dust controls.

3.0 FUGITIVE DUST CONTROLS

The following fugitive dust control measures were implemented during the period addressed by this Annual Report:

Plant Activity	Fugitive Dust Control Measures
Plant and Landfill Roadways	Roadways were watered as needed and speed control measures were implemented; material carried off plant property and deposited onto public highways by vehicular traffic or erosion by water was removed and disposed of properly.
CCR – Stackout Area	Emissions from this area are controlled by maintaining moisture in the material and watering as needed.
Landfill – unloading and placement of material	Unloading emissions were controlled by maintaining moisture in the material, taking precautionary measures (minimizing drop height) and watering as needed; spreading and compacting emissions were controlled by maintaining vehicle speed, maintaining moisture in the material, and watering as needed.
Landfill – wind erosion	Wind erosion control measures for open areas included: precautionary measures such as minimizing the amount of open area and pile height; compacting material as it was unloaded; maintaining moisture content of the materials, and watering as needed.
Bottom Ash Pond	Emissions were controlled by the inherent moisture of the material and timely loading of trucks; and watering as needed.

Note: *Implementation of control measures will not be necessary for roadways that are covered with snow and/or ice or if sufficient precipitation occurs to minimize or eliminate fugitive dust. Implementation of any control measures may be suspended if unsafe or hazardous driving conditions would be created by its use.*

4.0 CITIZEN COMPLAINT LOG

4.1 Plan Contacts

Generally, complaints made to the plant are by telephone and received by the PEC (Plan Contact). In the case of holiday, weekends, or other times when the PEC may not be onsite, the plant guard houses or plant general phone number may receive complaint information by telephone that is provided to the PEC at the earliest convenience. Complaints may also be made to TCEQ who in turn will contact the PEC. **No complaints were received by the Plant PEC during the period addressed by this Annual Report.**

4.2 Follow-up

All complaints will be entered into a log by the PEC with details noted such as the nature of the complaint, date, time, and other relevant details. All complaints will be followed up which may include: checking plant operations at the time of the event, reviewing inspection records, discussing with other plant personnel, reviewing weather data, collecting samples and contacting the person making the complaint to obtain additional information. **No complaint follow-up was necessary during the period addressed by this Annual Report.**

4.3 Corrective Action and Documentation

Corrective actions will be taken as needed and documented. If it is determined that the Plan needs to be amended as a result of the corrective actions, it will be amended in accordance with the Plan. If possible, the PEC will follow-up with the complainant and/or TCEQ to explain the findings of the complaint investigation, corrective actions or sampling results. Citizen complaints will be recorded in the annual Report. **No corrective actions due to complaints were necessary during the period addressed by this Annual Report.**

5.0 PLAN ASSESSMENT

The Plan will be periodically assessed to verify its effectiveness, and if necessary, amended. **The PEC reviewed the inspection records when preparing this Annual Report to assess the effectiveness of the Plan and determined that no additional or modified measures were warranted.**

6.0 RECORDKEEPING, NOTIFICATION and INTERNET REQUIREMENTS

6.1 Recordkeeping

The Annual Report and the Plan (and any subsequent amendment of the plan) will be kept in the facility's operating record as they become available. The Plan and files of all related information will be maintained in a written operating record at the facility for at least five years following the date of each occurrence, measurement, maintenance, corrective action, report, record or study. Only the most recent Plan must be maintained in the record. Files may be maintained on a computer or storage system accessible by a computer. One recordkeeping system may be used for multiple units if the system identifies each file by the name of each unit

6.2 Notification

The Director of the TCEQ will be notified within 30 days of when the Annual Report is placed in the operating record and on the publicly available internet site. This notification will be made before the close of business on the day the notification is required to be completed. "Before the close of business day" means the notification must be postmarked or sent by e-mail. If the notification deadline falls on a weekend or federal holiday, the notification is automatically extended to the next business day.

6.3 Internet Site Requirements

The most recent Annual Report will be placed on the facility's CCR website titled "CCR Rule Compliance Data and Information" within 30 days of placing it in the operating record.

3.3 – Run-on and Run-off Control System Plan, H.W. Pirkey Power Plant Landfill, October 2021

Run-on and Run-off Control System Plan

Table of Contents

1.0 INTRODUCTION

30 TAC 352.811 (Federal Regulation Title 40, Part 257.81) requires the owner or operator of an existing or new CCR landfill or any lateral expansion of an existing CCR landfill to comply with the following:

1. A run-on control system to prevent flow onto the active portion of the CCR unit during the peak discharge from a 24-hour, 25-year storm.
2. A run-off control system from the active portion of the CCR unit to collect and control at least the water volume resulting from a 24-hour, 25-year storm.
3. Run-off from the active portion of the CCR unit must be handled in accordance with the surface water requirements under §257.3-3.
4. Prepare initial and periodic run-on and run-off control system plans for the CCR unit according to the following timeframes:
   a. For existing CCR landfills, the owner or operator of the CCR unit must prepare the initial run-on and run-off control system plan no later than October 17, 2016.
   b. The owner or operator of the CCR unit must prepare periodic run-on and run-off control system plans every five (5) years.
5. Obtain a certification from a qualified professional engineer stating that the initial and periodic run-on and run-off control system plans meet the requirements of this section.
6. Comply with the recordkeeping requirements specified in §257.105(g), the notification requirements specified in §257.106(g), and the internet requirements specified in §257.107(g).

This Plan represents the 5-year revision of the original Run-on and Run-off Control System Plan, dated October 2016, and presents the regulatory-required materials as noted above. It is prepared for the existing landfill at AEP's H.W. Pirkey Power Plant in Hallsville, Texas. The landfill operation has installed and is maintaining the planned storm water control measures discussed in this plan. Attached Figure 1 – Overall Landfill Exhibit illustrates the landfill complex showing the storm water drainage systems as of October 2021.

2.0 RUN-ON CONTROLS

The purpose of run-on controls is to prevent the flow of water onto the active portion of the landfill during the peak discharge from a 24-hour, 25-year storm. The controls may be permanent or temporary, and their function may also change over time as landfill development proceeds. Controls must consider site conditions outside of the landfill footprint as well as site conditions within the landfill footprint.

2.1 Run-On Controls Outside the Landfill Footprint

2.1.1 Stormwater Perimeter Ditches

Perimeter drainage ditches around the active landfill provide controls to handle run-on from outside the active landfill footprint. The perimeter ditches define the limits of the active landfill ash disposal area/footprint. The perimeter ditches direct stormwater around the landfill pond to the south, and stormwater enters an unnamed tributary that flows 0.8 mile to Hatley Creek.

The perimeter ditches were designed to adequately handle the peak flow from a 24-hour, 25-year storm event. The design calculations are provided in Figure 3. Locations of the perimeter collection and diversion channels are also shown on Figure 1 – Overall Landfill Exhibit.

2.2 Run-On Controls Inside the Landfill Footprint

Run-on controls inside the landfill footprint are in place to ensure that stormwater from closed landfill cells does not enter the active landfill footprint.

2.2.1 Landfill Phasing and Construction Practices

The landfill at H.W. Pirkey Power Plant is broken into multiple cells, which are named based on the year they were constructed. Currently the active landfill cells are the 2012 Cell and 2015 Cell, and all other landfill cells have been capped and covered and are now closed. The closed landfill cells are graded to divert stormwater away from the active landfill cell, and into a storm sewer system with letdowns to capture water from the benches of the cell as well. See the figures in the appendix for the landfill configuration.

2.2.1.1 *Active Filling – 2012 and 2015 Cells*

Active filling currently occurs in the 2012 and 2015 Landfill Cells. Prior to the construction of the 2020 Cap & Cover Project, the access road along the west side of the cell served as a stormwater diversion berm. All capped and covered cells adjacent to the active area to the north and east are graded to divert water away from the active cell and ultimately into stormwater perimeter ditches that bypass the landfill pond. Run-on controls within the landfill footprint consist of underdrain systems. The underdrain system for the 2012 Cell discharges into the landfill pond, and the underdrain system for the 2015 Cell by-passes the pond. Run-off controls consist of a berm on the south and west sides of the active landfill cell. Also, a leachate collection system and a contact stormwater system serve to collect contact water from the cell and carry the water to the landfill pond.

2.2.1.2 *Future Filling – 2018 Cell*

Future filling will occur in Phase I of the 2018 Landfill Cell. The 2018 Cell is already constructed; however, active filling will only commence once the 2015 Cell is at capacity. Once the 2015 Cell is closed, it will slope away from the active landfill to a storm water letdown system that carries water to a perimeter ditch that bypasses the landfill pond. Run-on controls within the landfill footprint consist of an underdrain system that will discharge into a ditch that bypasses the landfill pond. Run-off controls consist of a perimeter HDPE lined ditch on the south and west sides of the landfill cell. Also, a leachate collection system will serve to collect leachate and contact stormwater from the cell and carry the contact water to the landfill pond.

2.2.2 Underdrain System

Underneath the active HDPE lined landfill cells, an underdrain system was installed to convey groundwater to perimeter ditches or the landfill pond. The underdrain systems consist of perforated HDPE pipes that are wrapped in SB57 rock, and then wrapped in filter fabric. The pipe systems are in a drainage layer that directs groundwater to the pipe systems, which are located under low areas or valleys in the liner, generally directly underneath the leachate pipe systems and perimeter stormwater ditches.

3.0 RUN-OFF CONTROLS

The run-off control system prevents flow (contact water) from leaving the active portion of the landfill during the peak discharge from a 24-hour, 25-year storm. Run-off control consists of the following aspects:

- Perimeter ditches
- Leachate collection system
- Landfill Pond
- Ash filling operation

Stormwater from the active landfill travels to the landfill pond via perimeter ditches, a contact stormwater pipeline, or through the leachate collection system via chimney drains. The leachate collection system is similar to the underdrain system, but differs in that it is located in a drainage layer above the HDPE liner of the cell, and conveys leachate from the active landfill cell to the landfill pond. Chimney drains in the 2015 Cell are utilized to capture stormwater from the top of the active landfill cell, and these chimney drains tie directly into the leachate system. Ash filling operation is managed such that contact water is directed to the chimney drains. The run-off control features are presented on the attached figures in the appendix. The following further describes the run-off control components.

3.1 Perimeter Ditches

Perimeter ditches are constructed around the active-phase and future filling areas. These ditches serve to convey stormwater from the active landfill to the landfill pond. All ditches were designed to adequately convey the water volume resulting from a 24-hour, 25-year storm event. The leachate collection system and ash filling operation use the ditches as part of their control systems as described below. The design calculations for the perimeter ditches are provided on Figure 3.

3.2 Leachate Collection System

The leachate collection system consists of 2-ft-thick minimum drainage layer over the landfill composite liner system and a network of perforated collection pipes. The composite liner system is sloped to promote drainage to the leachate collection pipe network, and the leachate collection pipe network discharges into the landfill pond. The leachate collection pipe network spacing is a function of the base grade liner slope, drainage layer permeability, and flow distance to collection pipes. The Hydraulic Evaluation of Landfill Performance (HELP) model was used in evaluating the pipe spacing with respect to contact water percolation to the leachate collection drainage layer, the minimum liner slope, and a selected pipe spacing or flow distance to a collection pipe.

Design of the chimney drains considered a 24-hour, 25-year storm event and a drainage area of approximately 10 acres for the active area. This resulted in a controlled discharge of storm water into the chimney drains and down to the leachate collection pipes.

3.3 Landfill Pond

All stormwater from the active landfill discharges into the landfill pond. The landfill pond was designed for the 24-hour, 25-year storm. However, the current landfill pond is serving as a total containment pond, meaning that stormwater that is collected in the pond is not treated and released downstream. Instead, water from the pond is pumped to the plant for evaporation. Also, an evaporator system is locally utilized in the pond. In case of emergencies, the pond does have an emergency spillway that can be utilized.

3.4 Ash Filling Operation

The ash filling operation must be performed in a manner to provide run-off control within the disposal cell such that the contact surface water reaches the leachate collection system. This involves grading the placed ash in a controlled manner to direct contact surface water flow toward the chimney drain structures in the interior portions of the disposal area. Ash grading must be directed away from the outside slopes, which have been capped.

4.0 PLAN REVIEW AND CHANGES IN FACILITY OPERATION

Landfill Owner and/or Operator will review and evaluate this Plan every five (5) years from initial plan preparation and when there are changes in the facility design, construction, operation, or maintenance that materially affect the facility's potential for run-on and run-off control. Amendments to the Plan made to address changes of this nature are referred to as technical or major amendments, and must be certified by a P.E. Non-technical amendments can be performed by the facility owner and/or operator. This Plan represents the 5-year revision of the original Run-on and Run-off Control System Plan, dated October 2016.

Technical and administrative amendments to the Plan have been and will continue to be documented on the Plan Review Log. Owner/Operator will make the necessary revisions to the Plan as soon as possible, but no later than six months after the change occurs. The Plan must be implemented as soon as possible following a technical amendment, but no later than six months from the date of the amendment. The Designated Person is responsible for initiating and coordinating revisions to the SPCC Plan.

Scheduled reviews and Plan amendments will be recorded in the Plan Review Log provided in Appendix 2. The log will be completed even if no amendment is made to the Plan as a result of the review.

5.0 PROFESSIONAL ENGINEER CERTIFICATION

This revised Plan, and all subsequent reviews and amended plans, must obtain certification from a qualified P.E. stating that the initial and subsequent run-on and run-off control system plans meet the requirements of 40 CFR 257. This certification in no way relieves the owner or operator of the facility of his/her duty to fully implement this Plan. The Professional Engineer Certification page is provided in Appendix C.

Professional Engineer Certification

Professional Engineer Certification

The Run-on and Run-off System Control Plan for the H.W. Pirkey Power Plant Landfill was prepared by Akron Consulting, LLC (TBPE Firm #14014). This Certification/Statement of Professional Opinion is limited to the information available to Akron at the time the Plan was written. On the basis of and subject to the foregoing, it is my professional opinion as a Professional Engineer licensed in the State of Texas, that the Plan has been prepared in accordance with good and accepted engineering practices as exercised by other engineers practicing in the same discipline(s), under similar circumstances and at the time and in the same locale. It is my professional opinion that the Plan was prepared, reviewed, and revised in accordance with the current requirements of 30 TAC 352.811 (Federal Regulation Title 40, Part 257.81).

The use of the words "certification" and/or "certify" in this document shall be interpreted and construed as a Statement of Professional Opinion, and is not and shall not be interpreted or construed as a guarantee, warranty or legal opinion. This certification in no way relieves the Owner or Operator of the facility of his/her duty to fully implement this Plan.

Engineer: Lane D. Roberts

Table of Contents

1.0 INTRODUCTION

30 TAC 352.811 (Federal Regulation Title 40, Part 257.81) requires the owner or operator of an existing or new CCR landfill or any lateral expansion of an existing CCR landfill to comply with the following:

1. A run-on control system to prevent flow onto the active portion of the CCR unit during the peak discharge from a 24-hour, 25-year storm.
2. A run-off control system from the active portion of the CCR unit to collect and control at least the water volume resulting from a 24-hour, 25-year storm.
3. Run-off from the active portion of the CCR unit must be handled in accordance with the surface water requirements under §257.3-3.
4. Prepare initial and periodic run-on and run-off control system plans for the CCR unit according to the following timeframes:
   a. For existing CCR landfills, the owner or operator of the CCR unit must prepare the initial run-on and run-off control system plan no later than October 17, 2016.
   b. The owner or operator of the CCR unit must prepare periodic run-on and run-off control system plans every five (5) years.
5. Obtain a certification from a qualified professional engineer stating that the initial and periodic run-on and run-off control system plans meet the requirements of this section.
6. Comply with the recordkeeping requirements specified in §257.105(g), the notification requirements specified in §257.106(g), and the internet requirements specified in §257.107(g).

This Plan represents the 5-year revision of the original Run-on and Run-off Control System Plan, dated October 2016, and presents the regulatory-required materials as noted above. It is prepared for the stack-out pad at AEP's H.W. Pirkey Power Plant in Hallsville, Texas.

2.0 RUN-ON CONTROLS

The purpose of run-on controls is to prevent storm water from entering into the stack-out pad from a 24-hour, 25-year storm.

2.1 Run-On Controls Outside the Stack-Out Pad

2.1.1 Diversion Dikes and Berms

An HDPE lined berm is located around the southern, western, and eastern sides of the stack-out pad. This berm provides a barrier that will not allow stormwater from the plant to enter the stack-out pad.

2.1.2 Stormwater Perimeter Ditches

A stormwater ditch to the east of the stack-out pad directs run-on water away from the proposed berm to the Auxiliary Surge Pond. See Appendix A for calculations. Stormwater to the south surface drains away from the berm to the south. Stormwater on the west side of the stack-out pad flows to the north.

3.0 RUN-OFF CONTROLS

The run-off control system prevents flow (contact water) from leaving the stack-out pad during a 24-hour, 25-year storm. Run-off control consists of the following aspects:

- Perimeter HDPE lined berm
- Perimeter Ditches
- Surge Pond

Stormwater from the stack-out pad travels to the surge pond via perimeter ditches. Perimeter HDPE lined berms help to ensure that stormwater is directed to these ditches and does not leave the stack-out pad. The surge pond accepts all stormwater from the stack-out pad, and water from the surge pond is utilized by the power plant in the FGD system.

3.1 Perimeter HDPE Lined Berm

The entire stack-out pad is surrounded on three sides by an HDPE lined berm. The berm is 1.5’ tall, with a 3’ top width. Not only does the berm prevent run-on from entering the stack-out pad, it directs stormwater inside the stack-out pad to enter perimeter ditches that carry contact water to the surge pond. The design calculations for the Perimeter HDPE lined berms are a function of the perimeter ditches, and calculations for the perimeter ditches are provided in Figure 1.

3.2 Perimeter Ditches

Perimeter ditches inside the stack-out pad transport contact water to the surge pond. One perimeter ditch on the west side of the stack-out pad discharges directly into the surge pond, while another perimeter ditch on the east side discharges into a culvert which discharges into a ditch that enters the auxiliary surge pond. The stack-out pad is graded to divert stormwater to these ditches. Design calculations for the perimeter ditches are provided in Figure 1.

3.3 Surge Pond

All stormwater from the stack-out pad enters the surge pond. Water in the surge pond is utilized by the power plant in the FGD system.

4.0 PLAN REVIEW AND CHANGES IN FACILITY OPERATION

Stack-out Pad Owner and/or Operator will review and evaluate this Plan every five (5) years from initial plan preparation and when there are changes in the facility design, construction, operation, or maintenance that materially affect the facility’s potential for run-on and run-off control. Amendments to the Plan made to address changes of this nature are referred to as technical or major amendments, and must be certified by a P.E. Non-technical amendments can be performed by the facility owner and/or operator. This Plan represents the 5-year revision of the original Run-on and Run-off Control System Plan, dated October 2016.

Technical and administrative amendments to the Plan have been and will continue to be documented on the Plan Review Log. Owner/Operator will make the necessary revisions to the Plan as soon as possible, but no later than six months after the change occurs. The Plan must be implemented as soon as possible following a technical amendment, but no later than six months from the date of the amendment. The Designated Person is responsible for initiating and coordinating revisions to the SPCC Plan.

Scheduled reviews and Plan amendments will be recorded in the Plan Review Log provided in Appendix 2. The log will be completed even if no amendment is made to the Plan as a result of the review.

5.0 PROFESSIONAL ENGINEER CERTIFICATION

This revised Plan, and all subsequent reviews and amended plans, must obtain certification from a qualified P.E. stating that the initial and subsequent run-on and run-off control system plans meet the requirements of 40 CFR 257. This certification in no way relieves the owner or operator of the facility of his/her duty to fully implement this Plan. The Professional Engineer Certification page is provided in Appendix C.

APPENDIX C:

Professional Engineer Certification

Professional Engineer Certification

The Run-on and Run-off System Control Plan for the H.W. Pirkey Power Plant Stack-Out Pad was prepared by Akron Consulting, LLC (Akron). This Certification/Statement of Professional Opinion is limited to the information available to Akron at the time the Plan was written. On the basis of and subject to the foregoing, it is my professional opinion as a Professional Engineer licensed in the State of Texas, that the Plan has been prepared in accordance with good and accepted engineering practices as exercised by other engineers practicing in the same discipline(s), under similar circumstances at the time, and in the same locale. It is my professional opinion that the Plan was prepared, reviewed, and revised in accordance with the current requirements of 30 TAC 352.811 (Federal Regulation Title 40, Part 257.81).

The use of the words “certification” and/or “certify” in this document shall be interpreted and construed as a Statement of Professional Opinion, and is not and shall not be interpreted or construed as a guarantee, warranty or legal opinion. This certification in no way relieves the Owner or Operator of the facility of his/her duty to fully implement this Plan.

Engineer: Lane D. Roberts

Registration Number: 105135

State: Texas

Date: 10/06/2021

Table of CONTENTS

Attachment A: Hydrology and Hydraulic Report East and West bottom Ash Ponds

1.0 OBJECTIVE

This report was prepared by AEP- Geotechnical Engineering Services (GES) section to fulfill requirements of 30 TAC 352.821 (40 CFR 257.82) for the hydrologic and hydraulic evaluation of CCR surface impoundments. This report is a summary of the periodic 5-year review of the initial evaluation.

2.0 DESCRIPTION OF THE CCR UNIT

The Henry W. Pirkey Power Station is located at 2400 FM 3251 and south of Hallsville, Texas.
It is owned and operated by Southwest Electric Power Company (SWEPCO). The facility operates two surface impoundments for storing CCR materials called the East Bottom Ash Pond (East BAP) and the West Bottom Ash Pond (West BAP).

The East BAP is located directly adjacent to and east of the West BAP. The East BAP receives sluiced bottom ash and has a surface area of 30.9 acres and a storage capacity of 188 acre-feet. The pond is almost entirely incised, with a reported maximum embankment height of 4 feet.

The West BAP, which also receives sluiced bottom ash, is located northwest of the main plant buildings and shares its eastern border with the western border of the East BAP. The West BAP receives sluiced bottom ash and has a surface area of 30 acres and a storage capacity of 188 acre-feet. The maximum embankment height is 25 feet. The main upstream embankment slopes are 3 feet horizontal to 1 foot vertical (3:1 H:V); while the main downstream slopes area 2.5:1 H:V.

3.0 INFLOW DESIGN FLOOD 257.82(a)(3)

The facility is classified as a Low Hazard Potential Dam. This classification has not changed since the initial evaluation. The Inflow Design Flood is the 100-year storm event which is 10.3 inches during a 24 hour period.

4.0 FLOOD CONTROL PLAN 257.82(c)

The only inflows from the inflow design flood is the direct rainfall within the ponds dikes. The design to safely pass the inflow design flood without overtopping the crest of the dam is based on the normal pool being at maximum normal operating pool and utilizing the principal spillway and emergency spillway to handle the 100-year design storm without overtopping the crest of the dike.

The analysis in Attachment A includes related excerpts from the 2015 Pirkey H&H Analysis report that provides the description of the spillway system, flood storage capacity, inflow peak discharge and volume, peak discharge from the facility and maximum pool elevation.

There has not been any changes to spillway system, flood storage capacity or rainfall estimates that would change the results presented in Attachment A.

The calculations show that the facility has the capacity to manage the inflow design flood, as well as large flood events.

HYDROLOGIC & HYDRAULIC CALCULATIONS

APPENDIX - A

Introduction

H.W. Pirkey Power Plant which is located in Hallsville, Texas is a subsidiary of American Electric Power. Plant operation requires a series of water impoundments utilized in the process of power generation, including the bottom ash ponds. The purpose of this report is to analyze and document the Hydrologic & Hydraulic characteristics of the East and West Bottom Ash Ponds at Pirkey Power Plant.

Hydrologic Methodology

This section describes the general outline of the hydrologic methodologies used to evaluate the total runoff tributary to the ponds. Specific characteristics of each pond are discussed under individual subheadings later in this report.

The East & West Ash Ponds are total containment ponds. Watershed areas contributing to the flow into these ponds are the ponds and berms/access roads themselves; in other words, these ponds have no additional runoff areas tributary to them. Therefore, a conservative approach is to adopt a curve number 100 and to consider that every inch of rainfall will directly increase the water surface elevation.

According to Natural Resource Conservation Service (formerly SCS) Technical Release 55, the peak flow is calculated using the formula:

$Q = (P-0.2S)^2 / (P+0.8S)$

where,

Q = runoff (inches)

P = rainfall (inches)

S = potential maximum retention after runoff begins (inches) = (1000/curve number) – 10

Applying a curve number of 100 to the formula above will ultimately result in $Q = P$ (because $S=0$); which implies that the total runoff contributing to the flow in each of the ponds is directly a function of the rainfall event.

Hydraulic Methodology

This section describes the general outline of the hydraulic methodologies used to analyze the storage capacity of the ponds. Specific characteristics of each pond are discussed under individual subheadings later in this report.

The plant’s CCR rules require that the ponds be able to accommodate the rainfall volume from a

100 year 24 hour storm without over topping. The normal operating level for each pond is established by other regulations, and it is set to 3 feet below the top of the embankment. Using actual field survey data, an elevation-area-storage table was developed for the ponds and is included in the tables section of this report. Hydraflow Hydrographs was utilized to evaluate storage capacity and the water surface elevations in each pond during the 100 year 24 hour rainfall event. The 25 year 24 hour rainfall event was analyzed as well.

Detailed Hydrologic & Hydraulic characteristics of the ponds are discussed below.

EAST ASH POND:

The East Ash Pond is located to the east of the rail road track and north of the Pirkey Power Plant. This is a coal combustion waste pond used to settle bottom ash that has been sluiced from the plant boiler. Field survey of the embankment around the impoundment indicates that the top of the embankment is at a minimum elevation of 357.0msl, which is consistent with original design drawings. Therefore, based on this top of embankment elevation, the normal operating level was established at 354.0msl. The watershed area contributing to the flow into this pond was estimated to be 29.63 acres.

The storage capacity for each pond was analyzed for a 100-yr, 24-hr rainfall event, which is 10.3 inches. Multiplying the acreage times the inches, the calculated volume of the rainfall event is 1,107,836 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 1,142,455 cf.

The storage capacity was also analyzed for a 25-yr, 24-hr rainfall event, which is 8.2 inches. The calculated volume of the rainfall event is 881,967 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 909,528 cf.

Water surface elevation was then calculated for the 100-yr, 24-hr rainfall event with a normal operating level (354.0msl) as the baseline elevation. Results from Hydraflow Hydrograph indicates that the water surface elevation during the 100-yr, 24-hr rainfall will be 354.99msl which is less than 357.0msl (embankment top). Results from the 25-yr, 24-hr rainfall event indicate the water surface elevation will be 354.79msl which is also less than 357.0msl (embankment top).

WEST ASH POND:

The West Ash Pond is located to the west of the rail road track and adjacent to the east ash pond. This is a coal combustion waste pond used to settle bottom ash that has been sluiced from the plant boiler. Field survey of the embankment around the impoundment indicates that the top of the embankment is at a minimum elevation of 357.0msl, which is consistent with original design drawings. Therefore, based on this top of embankment elevation, the normal operating level was established at 354.0msl. The watershed area contributing to the flow into this pond was estimated to be 33.44 acres.

As mentioned earlier the storage capacity for each pond was analyzed for a 100-yr, 24-hr rainfall event, which is 10.3 inches. Multiplying the acreage times the inches, the calculated volume of the rainfall event is 1,250,228 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 1,289,360 cf.

The storage capacity was also analyzed for a 25-yr, 24-hr rainfall event, which is 8.2 inches. The calculated volume of the rainfall event is 995,376 cf of water. When this rainfall event was modeled in Hydraflow Hydrographs, it generated a more conservative rainfall volume of 1,026,480 cf.

Water surface elevation was then calculated for the 100-yr, 24-hr rainfall event with a normal operating level (354.0msl) as the baseline elevation. Results from Hydraflow Hydrograph indicates that the water surface elevation during the 100-yr, 24-hr rainfall will be 355.01msl which is less than 357.0msl (embankment top). Results from the 25-yr, 24-hr rainfall event indicate the water surface elevation will be 354.81msl which is also less than 357.0msl (embankment top).

<u>Summary</u>

Water surface elevations calculated from Hydraflow Hydrographs are tabulated below:

SUMMARY OF POND HYDRAULIC CHARACTERISTICS

	TOP OF EMBANKMENT	OPERATING LEVEL	100YR-24HR WSEL	25YR-24HR WSEL
EAST ASH POND	357.0	354.0	354.99	354.79
WEST ASH POND	357.0	354.0	355.01	354.81

As evident from the table above, it is the opinion of Akron Consulting that the East & West Ash Ponds will serve to adequately contain the calculated rainfall events.

1.0 INTRODUCTION

This report was prepared by AEP- Geotechnical Engineering Services (GES) section, in part, to fulfill requirements of 40 CFR 257.83 and to provide South Western Electric Power Company (SWEPCO) and Pirkey Power Plant with an evaluation of the facility.

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas.

American Electric Power Service Corporation's Civil Engineering Division administers the Pirkey Power Plant's Dam Inspection and Maintenance Program (DIMP). As part of the DIMP, staff from the Geotechnical Engineering Services Section annually conducts dam and dike inspections. This report contains the inspection findings, observations, photographic descriptions, conclusions, and maintenance recommendations. This inspection report addresses the Bottom Ash Ponds at the Pirkey Power plant.

Mr. Brett Dreger, PE, a staff from the Geotechnical Engineering Services Section, conducted the Ash Ponds Inspection. Mr. William G. Carter, P.E. of AEP Plant Engineering Region 5, was the facility contact for the inspection and accompanied Mr. Brett Dreger during the inspection. The inspection was performed on October 22, 2019. Weather conditions were mostly sunny, with temperatures ranging from 50° F in the morning to 70° F in the afternoon. There was 2.5 inches of rainfall over the seven days prior to the inspection.

This report has been prepared by Mr. Brett Dreger, PE, under the direct supervision of Mr. Gary Zych, PE, AEP's Geotechnical section manager. The report presents: (i) Description of the impoundments, (i) Summary of Visual Observations; (ii) Conclusions; and (iii) Recommendations. Photographs identifying typical conditions, problem areas, items that need correction or requiring additional monitoring, have been selected from the inspection field photographic file and provided in the Attachments A and B, to this report.

2.0 DESCRIPTION OF IMPOUNDMENTS

2.1 EAST BOTTOM ASH POND

The East BAP CCR unit is located at the north end of the Plant and approximately 2,000 feet north-northwest of Brandy Branch Reservoir. The East BAP is partially incised below the existing natural ground surface with an embankment height of approximately 4 feet. The East BAP embankments are constructed of compacted clay on a 3:1 slope (3 feet horizontal, 1 foot vertical). The elevation of the top of the embankment around the perimeter of the East BAP is approximately 357 feet above msl, and the normal operating level is approximately 354 feet above msl. At the time of inspection, the EBAP was in service and the pool level was at 354.5 feet above msl. The interior bottom elevation of the East BAP is approximately 347.0 feet above msl.

Surface water elevation in the East BAP is controlled by a stop log regulated window cut into a concrete riser and a manually operated gate valve on a 36-inch-diameter discharge pipe at the southwest corner of the pond. Clear water overflow from the East BAP discharges through the 36-inch-diameter corrugated metal pipe into the 2.7- acre Secondary Bottom Ash Pond located directly south of the East BAP. Water in the Secondary Bottom Ash Pond is either pumped (recirculated) back into the boiler ash hopper, or gravity discharged through a pipe at the southwest corner of the Secondary Bottom Ash Pond into an unnamed intermittent tributary of Hatley Creek via Outfall 006 in accordance with Texas Pollutant Discharge Elimination System (TPDES) Permit No. WQ0002496000.

2.2 WEST BOTTOM ASH POND

The West BAP CCR unit is located at the north end of the Plant and approximately 3,000 feet northwest of Brandy Branch Reservoir. The West BAP embankments have a maximum height of approximately 25 feet and are constructed of compacted clay on a slope ranging from 2.5:1 (2.5 feet horizontal, 1 foot vertical) to 3:1. The elevation at the top of the embankment around the perimeter of the West BAP is approximately 357 feet above msl, and the normal operating level is approximately 354 feet above msl. At the time of inspection, the WBAP was out of service and the pool level was at 348.5 feet above msl. The interior bottom elevation of the East BAP is approximately 347 feet above msl.

Surface water elevation in the West BAP is controlled by a stop log regulated window cut into a concrete riser and a manually operated gate valve on a 36-inch-diameter discharge pipe at the southeast corner of the pond. Clear water overflow from the West BAP discharges through the 36-inch-diameter corrugated metal pipe into the 2.7- acre Secondary Bottom Ash Pond located southeast of the West BAP. Water in the Secondary Bottom Ash Pond is either pumped (recirculated) back into the boiler ash hopper, or gravity discharged through a pipe at the southwest corner of the Secondary Bottom Ash Pond into an unnamed intermittent tributary of Hatley Creek via Outfall 006 in accordance with Texas Pollutant Discharge Elimination System (TPDES) Permit No. WQ0002496000.

3.0 REVIEW OF AVAILABLE INFORMATION (257.83(b)(1)(i))

A review of available information regarding the status and condition of the CCR Ponds, which include files available in the CCR operating record, such as design and construction information, periodic structural stability assessments, previous 7 day inspection reports, 30-day instrumentation data, and previous annual inspections has been conducted. Based on the review of the data there were no signs of actual or potential structural weakness or adverse conditions.

4.0 CHANGES IN GEOMETRY SINCE LAST INSPECTION (257.83(b)(2)(i))

No modifications have been made to the geometry of the East and West Bottom Ash Ponds since the 2018 annual inspection. The geometry of the impoundment has remained essentially unchanged.

5.0 CHANGES THAT EFFECT STABILITY OR OPERATION (257.83(b)(2)(vii))

Based on interviews with plant personnel and field observations there were no changes to the East and West Bottom Ash Ponds since the last annual inspection that would affect the stability or operation of the impounding structure.

6.0 IMPOUNDMENT CHARACTERISTICS (257.83(b)(2)(iii, iv, v))

6.1 EAST BOTTOM ASH POND

Table 1 is a summary of the minimum, maximum, and present depth and elevation of the impounded water and CCR material since the previous annual inspection; the storage capacity of the impounding structure at the time of the inspection; and the approximate volume of the impounded water at the time of the inspection.

Table 1 Summary of Relevant Storage Information for East bottom Ash Pond

	Primary Ash Pond
Approximate **Minimum** depth of impounded water since last annual inspection	0.5ft (347.5)
Approximate **Maximum** depth of impounded water since last annual inspection	7.5ft (354.5)
Approximate **Present** depth of impounded water at the time of the inspection	7.5 ft (354.5)
Approximate **Minimum** depth of CCR since last annual inspection	0.5ft (347.5)
Approximate **Maximum** depth of CCR since last annual inspection	7.5ft (354.5)
Approximate **Present** depth of CCR at the time of the inspection	2.0ft (349.0)
Storage Capacity of impounding structure at the time of the inspection	188 acre-ft
Approximate volume of impounded water at the time of the inspection	40 Million Gallons at El. 354.5
Approximate volume of CCR at the time of the inspection	60,000 c.y.

6.2 WEST BOTTOM ASH POND

Table 2 is a summary of the minimum, maximum, and present depth and elevation of the impounded water and CCR material since the previous annual inspection; the storage capacity of the impounding structure at the time of the inspection; and the approximate volume of the impounded water at the time of the inspection.

Table 2 Summary of Relevant Storage Information for West Bottom Ash Pond

	Bottom Ash Storage Pond
Approximate **Minimum** depth of impounded water since last annual inspection	0.5ft (347.5)
Approximate **Maximum** depth of impounded water since last annual inspection	7.5ft (354.5)
Approximate **Present** depth of impounded water at the time of the inspection	1.5ft (348.5)
Approximate **Minimum** depth of CCR since last annual inspection	0.5ft (347.5)
Approximate **Maximum** depth of CCR since last annual inspection	7.5ft (354.5)
Approximate **Present** depth of CCR at the time of the inspection	1.0ft (348.0)

Storage Capacity of impounding structure at the time of the inspection	188 acre-ft
Approximate volume of impounded water at the time of the inspection	5 Million Gallons at El. 348.5
Approximate volume of CCR at the time of the inspection	15,000 c.y.

7.0 INSPECTION (257.83(b)(1)(ii))

7.1 GENERAL

The summary of the visual observations uses terms to describe the general appearance or condition of an observed item, activity or structure. Their meaning is understood as follows:

Good:	A condition or activity that is generally better or slightly better than what is minimally expected or anticipated from a design or maintenance point of view.
Fair or Satisfactory:	A condition or activity that generally meets what is minimally expected or anticipated from a design or maintenance point of view.
Poor:	A condition or activity that is generally below what is minimally expected or anticipated from a design or maintenance point of view.
Minor:	A reference to an observed item (e.g., erosion, seepage, vegetation, etc.) where the current maintenance condition is below what is normal or desired, but which is not currently causing concern from a structure safety or stability point of view.
Significant:	A reference to an observed item (e.g. erosion, seepage, vegetation, etc.) where the current maintenance program has neglected to improve the condition. Usually, conditions that have been previously identified in the previous inspections, but have not yet been corrected.
Excessive:	A reference to an observed item (e.g., erosion, seepage, vegetation, etc.) where the current maintenance condition is below or worse than what is normal or desired, and which may have affected the ability of the observer to properly evaluate the structure or particular area being observed or which may be a concern from a structure safety or stability point of view.

In addition, a "deficiency" is some evidence that a dam has developed a problem that could impact the structural integrity of the dam. There are four general categories of deficiencies. These four categories are described below:

1. Uncontrolled Seepage

Uncontrolled seepage is seepage that is not behaving as the design engineer has intended. An example of uncontrolled seepage is seepage that comes through or around the embankment and is not picked up and safely carried off by a drain. Seepage that is collected by a drain can still be uncontrolled if it is not safely collected and transported, such as seepage that is not clear. Seepage that is unable to be measured and/or observe it is considered uncontrolled seepage. [Wet or soft areas are not considered as uncontrolled seepage, but can lead to this type of deficiency. These areas should be monitored frequently.]

2. Displacement:

   Displacement of the embankment is large scale movement of part of the dam. Common signs of displacement are cracks, scraps, bulges, depressions, sinkholes and slides.

3. Blockage of Control Features:

   Blockage of Control Features is the restriction of flow at spillways, decant or pipe spillways, or drains.

4. Erosion:

   Erosion is the gradual movement of surface material by water, wind or ice. Erosion is considered a deficiency when it is more than a minor routine maintenance item.

7.2 VISUAL INSPECTION (257.83(b)(2)(i))

A visual inspection of the CCR Ponds Complex was conducted to identify any signs of distress or malfunction of the impoundment and appurtenant structures. Specific items inspected included all structural elements of the dam such as upstream and downstream slopes, crest, and toe.

EAST BOTTOM ASH POND

In general, the crest, interior and exterior slopes of the dike appear to be in satisfactory and stable condition. No significant change to the exterior slope was noted from the previous inspection. No significant settlement or misalignment was observed. Seeps were not observed during the inspection. No animal burrows were observed during the inspection.

1. Photographs No. 1 illustrates the crest area and interior slopes of the eastern side of the east bottom ash pond. The crest has signs of rutting form truck traffic and the vegetation on the interior slopes is overgrown. There were no other signs of settlement, misalignment and cracking observed.

2. Photographs No. 2 illustrates the condition of the perimeter ditch on the east side of the pond. The perimeter ditch shows signs of a washout from a recent rain event. The sediment and vegetation buildup from the washout is causing standing water in the bottom of the ditch.

3. Photograph No. 3 shows the general condition of the interior area of the East Bottom Ash Pond. The east bottom ash pond was in service at the time of inspection.

4. Photograph No. 4 illustrates the typical condition of the crest area on the north side of the pond. In general, the crest area appeared to be in satisfactory condition with no signs of rutting, cracks or misalignment.

5. Photographs No. 5 shows the general condition of the interior slopes of the east bottom ash pond. The slope appeared in satisfactory and stable condition. There were no signs of settlement, misalignment, sloughing or erosion.

6. The overflow discharge structure walkway, railings, metal decking, and visible concrete were found to be in satisfactory, functional condition. However, there was overgrown vegetation adjacent to the access platform. Photographs No. 6 illustrate the access stairs, metal walkway, metal deck, and concrete structure of the overflow discharge structure.

Overall the facility is in satisfactory condition. The impoundment is functioning as intended with no signs of potential structural weakness or conditions which may be disrupting to the safe operation of the impoundment.

WEST BOTTOM ASH POND

In general, the crest, interior and exterior slopes of the dike appear to be in satisfactory and stable condition. No significant change to the exterior slope was noted from the previous inspection. No significant settlement or misalignment was observed. Seeps were not observed during the inspection. No animal burrows were observed during the inspection.

7. Photographs No. 7 and 8 illustrate a typical overview of the dike crest. The crest appears to be in good and stable condition. There were no other signs of settlement, misalignment and cracking observed.

8. Photographs No. 9 and 10 illustrate the condition of the interior slopes and vegetation management of the west bottom ash pond. The interior slopes and vegetation of the interior dikes appeared to be in satisfactory and stable condition.

9. Photograph No. 11 show the general condition of the interior area of the west bottom ash pond. There is some overgrown vegetation surrounding the sluicing pipe platform that extends out into center of the pond. The west bottom ash pond was out of service at the time of inspection.

10. The overflow discharge structure walkway, railings, metal decking, and visible concrete were found to be in satisfactory, functional condition. However, there was some overgrown vegetation adjacent to the access stairs. Photographs No. 12 illustrates the overgrown vegetation around the access metal walkway, metal deck, and concrete structure of the overflow discharge structure.

11. Photographs No. 13, 14 and 16 shows the general condition of the exterior slope and toe areas of the west bottom ash pond. The slopes appeared in satisfactory and stable condition. There were no signs of wet areas, settlement, misalignment, sloughing or erosion. The north and west exterior slopes had overgrown vegetation.

12. Photograph No. 15 shows a significant tire rut on the upper south exterior slope near the crest. The tire rut is likely caused from recent mowing activities.

13. Photograph No. 17 shows the development erosion formed along the edge of an access ramp on the southeast side of pond. There also are some minor erosion formed on another access ramp at the southwestern corner of the embankment. The erosion is taking place in

areas along these access ramps to the crest, but does not appear to be a detrimental condition to the integrity of the structure.

Overall the facility is in satisfactory condition. The impoundment is functioning as intended with no signs of potential structural weakness or conditions which maybe disrupting to the safe operation of the impoundment.

7.3 INSTRUMENTATION (257.83(b)(2)(ii))

The monitoring instrumentation for the West Bottom Ash Pond include open pipe type piezometers. The piezometers are located in the crest areas and are flush mount design. There is no monitoring instrumentation for the East Bottom Ash Pond.

Monitoring instrumentation data is reviewed as part of the annual inspection program for the Pirkey Bottom Ash Ponds. The maximum levels measured since the last inspection of the West Bottom Ash Pond are reported below:

Pond Name	Crest Elevation msl	Boring/Piezometer	Min/Max/Present WSEL msl
West Bottom Ash	357.0	W-1	323.80/338.31/323.80
West Bottom Ash	357.0	W-3	319.27/328.85/319.27

Piezometers W-1 and W-3 are in service and water level readings are measured on a monthly basis. The readings of the piezometers are in good agreement with the operating levels of the pond and are within the tolerance that would provide for a greater than minimum required stability for a facility of this type.

8.0 SUMMARY OF FINDINGS

Based on the visual observations during the inspection, the dam and appurtenances are generally in good condition. Specific conclusions related to this inspection include:

- There is no evidence of distress that would indicate the possibility of immediate sliding, slope instability, settlement, misalignment or cracking of the bottom ash pond embankments. As such it is concluded that the dam and dikes are performing as designed.
- Overall, the slope conditions of the dam and levees are generally fair with the exception of some tire ruts caused from truck traffic and mowing activities. These areas overtime can lead to significant erosion and stability problems.
- Vegetation management for the facilities is considered satisfactory. However, some areas are overgrown and the vegetation should be maintained at least 25 feet from the toe of the embankment.

9.0 RECOMMENDATIONS

A summary of our recommendations for general maintenance and continued monitoring, as well as any recommendations for remedial activities, is provided as follows:

9.1 MAINTENANCE ITEMS

The following maintenance items were identified during the visual inspection:

- Overall, the slope conditions of the dam and levees are generally fair with the exception of some tire ruts caused from truck traffic and mowing activities. These areas overtime can lead to significant erosion and stability problems.
- Vegetation management for the facilities is considered satisfactory. However, some areas are overgrown and the vegetation needs to be maintained at least 25 feet from the toe of the embankments.

9.2 ITEMS TO MONITOR

- No Items to monitor

9.3 DEFICIENCIES (257.83(b)(2)(vi))

There were no deficiencies or signs of structural weakness or disruptive conditions that were observed at the time of the inspection that would require additional investigation or remedial action. There were no deficiencies noted during any of the quarterly inspections. If any of these conditions occur before the next annual inspection contact AEP Geotechnical Engineering immediately.

If you have any questions with regard to this report, please contact Brett Dreger at Audinet: 200-2258 or Gary Zych at Audinet: 200-2917.

1.0 INTRODUCTION

This report was prepared by Akron Consulting, LLC for the AEP - Geotechnical Engineering Services (GES) section, in part, to fulfill requirements of 40 CFR 257.84 and to provide the H.W. Pirkey Power Plant an evaluation of the facility.

Mr. Lane Roberts, P.E. performed the 2020 inspection of the landfill at the H.W. Pirkey Plant. This report is a summary of the inspection and an assessment of the general condition of the facility. Mr. Ron Franklin of the plant was the facility contact for this inspection, which was performed on November 5, 2020. Weather conditions were partly cloudy with light winds, and the average temperature was in the low 70's (°F). Portions of the landfill had been recently mowed.

2.0 DESCRIPTION OF LANDFILL

The H.W. Pirkey Power Plant is located in southern Harrison County, approximately 6 miles southeast of Hallsville, Texas, as shown in Figure 1 – Vicinity Map in Attachment A. The CCR Landfill is located southwest of the main plant, between the Sabine Mine coal pile to the north and the Landfill Run-off Pond to the South. The overall features of the landfill were categorized into the following components as a means of organizing the inspection and reporting:

- Closed Landfill Area (1984, 1987, 1993, 1995, 1997, 1999, and 2005 Cells)
- Inactive Landfill Areas (2012, 1985 Pond Cell and 1993 Cell)
- Active Landfill Disposal Areas (2015 Cell)
- Landfill Construction Area for 2018 Cell
- Storm Water Drainage Ditches

These features, including the approximate limits of each area, are shown on Figure 2 – Site Map in Attachment A. Selected photographs taken during the inspection and used to illustrate the visual observations presented in the report are presented in Attachment B. Additional inspection photos not included in the report can be made available to the plant upon request.

In general, the southwestern area of the landfill is active. The remainder of the landfill area is considered closed and has a grass or turf cover present or is considered inactive. The landfill was developed around an existing oil/gas well known as the Mohan well which is located near the eastern edge of the landfill. Perimeter ditches carry non-contact water to the surrounding natural drainage courses. Multiple catch basins collect and convey non-contact water via "let-down" piping systems. All contact water is directed towards the Landfill Run-off Pond. The four leachate collection discharge pipes outlet on the southern end of the landfill, and all leachate water is conveyed to the Landfill Runoff Pond to the south. There are two parallel ditches on the western boundary of the landfill area, one ditch for contact water and one ditch for non-contact water.

Material to be placed in the active portions of the landfill is hauled via dump trucks on a haul road, which runs along the north and western edge of the landfill area. The active portion of landfill area has vertical chimney drains, which connect to the leachate collection system. Surface water runoff from the active landfill areas is collected and routed to the Landfill Runoff Pond via the chimney drains.

3.0 REVIEW OF AVAILABLE INFORMATION (257.84(b) (1)(i))

A review of available information regarding the status and condition of the landfill, which includes files available in the operating record, such as design, and construction information, previous 7-day inspection reports, and previous annual inspections have been conducted. Based on the review of the data, there were no signs of actual or potential structural weakness or adverse conditions.

4.0 INSPECTION (257.84(b)(1)(ii))

4.1 CHANGES IN GEOMETRY SINCE LAST INSPECTION (257.84(b)(2)(i))

No modifications occurred to the geometry of the landfill since the 2019 annual inspection. The only construction that has occurred since the 2019 annual inspection is the installation of a new 2019 Cap and Cover Area with ClosureTurf, along with the installation of additional rain flap, but neither of these activities changed the overall geometry of the landfill.

4.2 VOLUME (257.84(b)(2)(ii))

The total volume of ash disposed at the landfill as of November 2020 was estimated to be approximately 15.5 million cubic yards.

4.3 DEFINITIONS OF VISUAL OBSERVATIONS AND DEFICIENCIES

This summary of the visual observations uses terms to describe the general appearance or condition of an observed item, activity or structure. The meaning of these terms is as follows:

Good:	A condition or activity that is generally better or slightly better than what is minimally expected or anticipated from a design or maintenance point of view.
Fair/Satisfactory:	A condition or activity that generally meets what is minimally expected or anticipated from a design or maintenance point of view.
Poor:	A condition or activity that is generally below what is minimally expected or anticipated from a design or maintenance point of view.
Minor:	A reference to an observed item (e.g., erosion, seepage, vegetation, etc.) where the current maintenance condition is below what is normal or desired, but which is not currently causing concern from a structure safety or stability point of view.
Significant:	A reference to an observed item (e.g. erosion, seepage, vegetation, etc.) where the current maintenance program has neglected to improve the condition. Usually, these are conditions that have been identified in the previous inspections, but have not been corrected.
Excessive:	A reference to an observed item (e.g., erosion, seepage, vegetation, etc.) where the current maintenance condition is above or worse than what is normal or desired, and which may have affected the ability of the observer to properly evaluate the structure or particular area being observed or which may be a concern from a structure safety or stability point of view.

This document also uses the definition of a “deficiency” as referenced in the CCR rule section §257.84(b)(5) Inspection Requirements for CCR Landfills. This definition has been assembled using the CCR rule preamble as well as guidance from MSHA, “Qualifications for Impoundment Inspection” CI-31, 2004. These guidance documents further elaborate on the definition of deficiency. Items not defined by deficiency are considered maintenance or items to be monitored.

A “deficiency” is some evidence that a landfill has developed a problem that could impact the structural integrity of the landfill. There are four general categories of deficiencies. These four categories are described below:

1. Uncontrolled Seepage (Leachate Outbreak)
   Leachate outbreak is the uncontrolled release of leachate from the landfill.
2. Displacement of the Embankment
   Displacement of the embankment is large scale movement of part of the landfill. Common signs of displacement are cracks, scraps, bulges, depressions, sinkholes and slides.
3. Blockage of Control Features
   Blockage of Control Features is the restriction of flow at spillways, decant or pipe spillways, or drains.
4. Erosion
   Erosion is the gradual movement of surface material by water, wind or ice. Erosion is considered a deficiency when it is more than a minor routine maintenance item.

4.4 VISUAL INSPECTION (257.84(b)(1)(ii))

A visual inspection of the landfill was conducted to identify any signs of distress or malfunction of the landfill and appurtenant structures. Specific items inspected included all structural elements of the landfill perimeter berms, temporary and final covers, drainage features, open cells, and appurtenances such as chimney drains etc.

Overall, the facility is in good condition. The landfill is functioning as intended with no signs of potential structural weakness or conditions which are disruptive to the safe operation of the landfill. Inspection photos are included in Attachment B. Additional pictures taken during the inspection can be made available upon request. A site map presenting locations of the inspection observations is included as Figure 2 in Attachment A.

Closed Landfill Areas (1984, 1987, 1993, 1995, 1997, 1999, and 2005 Cells)

1. In general, surface water runoff from the cap was draining as designed. There were no signs of erosion, undermining, scarps or sloughs in the surface vegetation covering the top and side slope areas. Only minor hog rutting damage was found on the north slope of the 2005 Cell.
2. The closed landfill areas were observed to have a thick stand of grass cover over the majority of the capped area. The landfill cover of cells 1984, 1987, 1993, 1995, 1999 and 2005 were well vegetative. Areas with less vegetation had recently been re-seeded and hay mulched.
3. There were no signs of settlement, movement or distress of the landfill area. Access roads on top and adjacent to the landfill area were in good condition.
4. There is ponded water in the perimeter ditch on the north side of the landfill. However, a pump and pump house had recently been installed to pump this water around the landfill.

Inactive Landfill Disposal Areas (2012, 1985 Pond Cell and 1993 Cell)

5. The 36-inch-diameter and 18-inch-diameter leachate collection discharge pipe outlets near the south end of the 2012 Cell were unobstructed and free-flowing.
6. A temporary soil cover consisting of a red sandy-clay material has been placed for an erosion protection measure on the south slope. The vegetation on this area was in good condition. In addition to the soils cover, the lower adjacent area has been recently covered with a geo-membrane rain flap material for erosion protection. All disturbed soil areas were re-seeded and hay mulched as part of this installation.
7. The western-most top portion of the 2012 Cell area was covered with 18-inches of topsoil to complete the 2018 cap system at the end of 2019, and the vegetation is in good condition. As noted previously, a second area to the west was also capped and covered with ClosureTurf at the end of 2019.
8. The 1993 Cell was still covered with a geo-membrane rain flap material that appeared to be in good condition.
9. There is standing water at the surface near the groundwater interceptor drain manhole on the southern side of the landfill. Groundwater is also pushing up on the liner system in the perimeter ditch near the groundwater interceptor drain manhole. According to plant personnel, the groundwater in this area will be lowered once the Landfill Runoff Pond is lowered.

Active Landfill Disposal Areas (2015 Cell)

10. During the inspection, the lower portion of the active area was being re-graded so that a geo-membrane rain flap could be installed. The chimney drains were functioning as designed and there was no evidence of pooling water around the drains. In general, the chimney drain consists of bottom ash placed by filling in a 10-foot-diameter circle with a perforated drainpipe wrapped in filter fabric placed in the center that is connected to the leachate discharge pipes.
11. The CCR materials are being placed and graded in such a manner that any runoff from the active landfill area is collected, contained and drained through the chimney drain system.
12. The lower slopes of the 2015 active cell have been covered with a 20-mil geomembrane rain flap material for erosion protection and to minimize contact water in the perimeter ditches. This will be replaced with ClosureTurf in the near future.

2018 Landfill Cell Construction

13. The 2018 Landfill Cell bottom liner system has not been modified since the 2019 inspection. Once the leachate collection system is installed and a protective cover layer is in place, the cell will be ready for accepting CCR waste.
14. Based on the current conditions, storm water runoff from the liner area and perimeter ditches is considered non-contact water and is diverted around the Landfill Runoff Pond.

Storm Water Drainage Ditches

15. Concrete slope protection installed on the inlet side of two, 36-inch-diameter culverts, which discharge leachate and contact water into the Landfill Runoff Pond was observed to be broken and distressed. The geomembrane landfill liner extends underneath the entire length of the culverts and does not appear to be damaged. An access road is present over the top of the culverts. According to plant personnel, this will be repaired as part of the 2021 cap and cover project.

16. A non-contact water ditch runs along the eastern edge of the landfill area. The vegetation along this ditch was in good condition, with some isolated areas that had recently been re-seeded and hay mulched. There was no evidence of erosion, obstructions or poor drainage conditions.
17. A contact water ditch runs along the western edge of the landfill area and is lined with a geomembrane. The ditch was observed to be clear of any obstructions and will be reclaimed as part of the 2020 cap and cover project.
18. A non-contact storm water ditch which is located along the western edge of the landfill is lined with a geomembrane material. Runoff from the 2005 Cell is collected into a 36-inch-diameter conduit and this conduit discharges into the non-contact water ditch. An earthen berm armored with riprap material has been placed at the end of the non-contact water ditch to divert flow away from the toe area of the Landfill Runoff Pond Dam. Small holes about 2 inches in diameter have been cut into the geomembrane to allow any trapped groundwater under the geomembrane to drain and prevent floating of the geomembrane liner.
19. A non-contact storm water ditch runs along the western edge and southern edge of the landfill that is covered with a rain flap material. Runoff from the lower outside slope of the 2015 Cell is collected into a lined ditch and then discharges into the non-contact water ditch on the western side of the landfill.

4.5 CHANGES THAT EFFECT STABILITY OR OPERATION (257.84(b)(2)(iv))

Based on interviews with plant personnel and field observations, there were no changes to the landfill since the last annual inspection that would affect the stability of the landfill.

5.0 SUMMARY OF FINDINGS

5.1 GENERAL OBSERVATIONS

The following general observations were identified during the visual inspection:

1) In general, the landfill is functioning as intended and the active cell, inactive cells, closed areas, and storm water ditches are in good condition. The Plant is performing regular maintenance and inspections as required. Several maintenance items have been noted and are described in Section 5.2.

5.2 MAINTENANCE ITEMS

The following maintenance items were identified during the visual inspection, see site map for locations. Contact GES for specific recommendations regarding repairs:

1) Remove the broken and distressed concrete slab slope protection at the inlet of the two, 36-inch-diameter culverts. After removing the concrete slab, inspect this area for any damages. After inspection, replace the inlet of the culverts.

2) Drain the ground water pipes at the south end of the landfill into the Landfill Runoff Pond.

3) The hog rutting damage on the north slope of the 2005 Cell should be repaired. Any bare areas should be re-seeded. The ponded water in the north perimeter ditch should be pumped around the landfill with the recently installed pump.

5.3 ITEMS TO MONITOR

The following items were identified during the visual inspection as items to be monitored:

- None identified as part of this inspection.

5.4 DEFICIENCIES (257.84(b)(2)(iii))

There were no signs of structural weakness or disruptive conditions observed at the time of the inspection that would require additional investigation or remedial action. There were no deficiencies noted during this inspection or during any of the periodic 7-day inspections.

A deficiency is defined as either:

1) Uncontrolled seepage (leachate outbreak),
2) Displacement of the embankment,
3) Blockage of control features, or
4) Erosion, more than minor maintenance.

If any of these conditions occur before the next annual inspection, contact the Geotechnical Engineering Services (GES) section immediately.

1.0 INTRODUCTION

This report was prepared by Akron Consulting, LLC for the AEP - Geotechnical Engineering Services (GES) section, in part, to fulfill requirements of 40 CFR 257.84 and to provide the H.W. Pirkey Power Plant an evaluation of the facility.

Mr. Lane Roberts, P.E. performed the 2020 inspection of the FGD Stackout Area at the H.W. Pirkey Plant. This report is a summary of the inspection and an assessment of the general condition of the facility. Mr. Ron Franklin of the plant was the facility contact for this inspection, which was performed on November 5, 2020. Weather conditions were partly cloudy with light winds, and the average temperature was in the low 70's (°F).

2.0 DESCRIPTION OF LANDFILL

The H.W. Pirkey Power Plant is located in southern Harrison County, approximately 6 miles southeast of Hallsville, Texas, as shown in Figure 1 – Vicinity Map in Attachment A. The FGD Stackout Area is located due west of the main plant. The FGD Stackout Area is a designated CCR Unit that is subject to 40 CFR 257.84 Inspection Requirements for CCR Landfills. The FGD Stackout Area is designed to temporarily hold a stockpile of Coal Combustion Residuals (CCR) material until it is hauled off by dump trucks for permanent disposal in a separate landfill. A radial arm stacker deposits the CCR material on the ground surface within the footprint of the FGD Stackout Area. A stone berm with a geomembrane cover exists around the perimeter of the FGD Stackout Area to contain any contact water. All contact water drains by gravity to the lower Surge Pond or the Auxiliary Surge Pond for circulation back to the plant. There is a concrete pad used for washing the tires of dump trucks that drive into the FGD Stackout Area.

These features, including the approximate limits of each area, are included in Figure 2 – Site Map in Attachment A. Selected photographs taken during the inspection and used to illustrate the visual observations presented in the report are presented in Attachment B. Additional inspection photos can be made available to the Plant upon request.

3.0 REVIEW OF AVAILABLE INFORMATION (257.84(b)(1)(i))

A review of available information regarding the status and condition of the FGD Stackout Area which includes files available in the operating record, such as design and construction information, previous periodic structural stability assessments, previous 7 day inspection reports, and previous annual inspections has been conducted. Based on the review of the data, there were no signs of actual or potential structural weakness or adverse conditions.

4.0 INSPECTION (257.84(b)(1)(ii))

4.1 CHANGES IN GEOMETRY SINCE LAST INSPECTION (257.84(b)(2)(i))

No modifications have been made to the geometry of the FGD Stackout Area since the 2019 annual inspection. However, in order to minimize erosion and contact storm water, the plant has recently installed a geomembrane rain flap on the western side of the area to direct non-contact storm water around the Surge Pond, but this did not change the overall geometry of the FGD Stackout Area.

4.2 VOLUME (257.84(b)(2)(ii))

The total volume of ash that has passed through the FGD Stackout Area since the 2019 inspection was estimated at approximately 175,000 cubic yards. At the time of the inspection, it was estimated that about 200 cubic yards were stockpiled at the FGD Stackout Area.

4.3 DEFINITIONS OF VISUAL OBSERVATIONS AND DEFICIENCIES

This summary of the visual observations uses terms to describe the general appearance or condition of an observed item, activity or structure. The meaning of these terms is as follows:

Good:	A condition or activity that is generally better or slightly better than what is minimally expected or anticipated from a design or maintenance point of view.
Fair/Satisfactory:	A condition or activity that generally meets what is minimally expected or anticipated from a design or maintenance point of view.
Poor:	A condition or activity that is generally below what is minimally expected or anticipated from a design or maintenance point of view.
Minor:	A reference to an observed item (e.g., erosion, seepage, vegetation, etc.) where the current maintenance condition is below what is normal or desired, but which is not currently causing concern from a structure safety or stability point of view.
Significant:	A reference to an observed item (e.g. erosion, seepage, vegetation, etc.) where the current maintenance program has neglected to improve the condition. Usually, these are conditions that have been identified in the previous inspections, but have not been corrected.
Excessive:	A reference to an observed item (e.g., erosion, seepage, vegetation, etc.) where the current maintenance condition is above or worse than what is normal or desired, and which may have affected the ability of the observer to properly evaluate the structure or particular area being observed or which may be a concern from a structure safety or stability point of view.

This document also uses the definition of a "deficiency" as referenced in the CCR rule section §257.84(b)(5) Inspection Requirements for CCR Landfills. This definition has been assembled using the CCR rule preamble as well as guidance from MSHA, "Qualifications for Impoundment Inspection" CI-31, 2004. These guidance documents further elaborate on the definition of deficiency. Items not defined by deficiency are considered maintenance or items to be monitored.

A "deficiency" is some evidence that a landfill has developed a problem that could impact the structural integrity of the landfill. There are four general categories of deficiencies. These four categories are described below:

1. Uncontrolled Seepage (Leachate Outbreak)

   Leachate outbreak is the uncontrolled release of leachate from the Landfill.

2. Displacement of the Embankment

   Displacement of the embankment is large scale movement of part of the landfill. Common signs of displacement are cracks, scarps, bulges, depressions, sinkholes and slides.
3. Blockage of Control Features

   Blockage of Control Features is the restriction of flow at spillways, decant or pipe spillways, or drains.
4. Erosion

   Erosion is the gradual movement of surface material by water, wind or ice. Erosion is considered a deficiency when it is more than a minor routine maintenance item.

4.4 VISUAL INSPECTION (257.84(b)(1)(ii))

A visual inspection of the FGD Stackout Area was conducted to identify any signs of distress or malfunction of the landfill and appurtenant structures. Specific items inspected included all structural elements of the landfill perimeter berms, ditches and drainage patterns.

Overall the facility is in good condition. The FGD Stackout Area is functioning as intended with no signs of potential structural weakness or conditions, which are disruptive to the safe operation of the landfill. Inspection photos are included in Attachment B. Additional pictures taken during the inspection can be made available upon request. A site map presenting locations of the inspection observations is included as Figure 2 in Attachment A.

1. The gravel berm with a geomembrane cover appeared to be in good condition. There was no evidence of holes, air/water pockets, or other signs of distress noted on the geomembrane.

2. Surface water runoff from along the eastern gravel berm with a geomembrane cover is conveyed underneath an access road via a steel pipe culvert. Storm water from this culvert outlets onto a concrete slab with curb walls underneath the supports for the conveyor belt that supplies the radial arm stacker. A section of these curb walls has been notched to allow surface water runoff to drain to the Auxiliary Surge Pond. The steel culvert was not obstructed, but the area upstream of the culvert should be re-graded to maintain positive drainage to the culvert.

3. There is no vegetal cover on the FGD Stackout Area due to material constantly being stockpiled and removed.

4. The geomembrane rain flap that was recently installed is functioning in good condition. All contact water adjacent to the rain flap is directed away from it to the Surge Pond.

5. Vehicle traffic enters the site from the south end via a gravel access ramp, which is also functioning in good condition. This ramp also serves as a berm to ensure the contact water in the FGD Stackout Area is contained and directed to the Surge Pond.

6. A minor obstruction was observed in the concrete ditch on the north end, which should be removed. Minor erosion was also observed where the FGD Stackout Pad surface drains into the Auxiliary Surge Pond, which should be repaired.

4.5 CHANGES THAT EFFECT STABILITY OR OPERATION (257.84(b)(2)(iv))

Based on interviews with plant personnel and field observations, there were no changes to the FGD Stackout Area since the last annual inspection that would affect the stability of the facility.

5.0 SUMMARY OF FINDINGS

5.1 GENERAL OBSERVATIONS

The following general observations were identified during the visual inspection:

1) In general, the FGD Stackout Area is functioning as intended and is in good condition. The Plant is performing regular maintenance and inspections as required. A few minor maintenance items have been noted and described in Section 5.2.

5.2 MAINTENANCE ITEMS

The following maintenance items were identified during the visual inspection (see site map for locations). Contact GES for specific recommendations regarding repairs:

1) The area upstream of the culvert that drains the eastern perimeter ditch should be re-graded to maintain positive drainage to the culvert.
2) The minor obstruction in the concrete ditch on the north end should be removed.
3) Repair the erosion rills that have formed from the stackout pad to the Auxiliary Surge Pond. This area shall be backfilled properly due to the presence of shallow pipelines in this area. This erosion is considered a minor maintenance item.

5.3 ITEMS TO MONITOR

There are no items to monitor as a result of observations made during this visual inspection.

5.4 DEFICIENCIES (257.84(b)(2)(iii))

There were no signs of structural weakness or disruptive conditions observed at the time of the inspection that would require additional investigation or remedial action. There were no deficiencies noted during this inspection or during any of the periodic 7-day inspections. A deficiency is defined as either:

1) Uncontrolled seepage (leachate outbreak),
2) Displacement of the embankment,
3) Blockage of control features, or
4) Erosion, more than minor maintenance.

If any of these conditions occur before the next annual inspection, contact the Geotechnical Engineering Services (GES) section immediately.

1. Objective

This report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to assess the adequacy of the groundwater monitoring well network included in the Coal Combustion Residual (CCR) requirements, as specified in Code of Federal Regulations (CFR) 40 CFR 257.91, for the East Bottom Ash Pond (BAP) CCR Unit at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The CCR requirements include an evaluation of the adequacy of the groundwater monitoring well network to characterize groundwater quality up and down gradient of the CCR unit and an evaluation of whether the CCR unit meets up to 5 location restrictions, which include: the base of the CCR unit is 5 feet (ft) above and isolated from the uppermost aquifer, the CCR unit may not be located in a wetland, within 200 ft of the damage zone of a fault that has displacement during the Holocene, within a seismic impact zone, or in an unstable area.

Four regulated CCR units associated with the Plant were identified for review, which include the West BAP, East BAP, Stack Out Area, and Landfill (**Figure 2**). This report summarizes the evaluation of the groundwater monitoring well network in the uppermost aquifer at the East BAP (Site). The evaluation of the location restriction criteria is not included in this report and will be completed under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the East BAP CCR unit, as well as publically-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on all documents reviewed and will further describe the uppermost aquifer, include an evaluation of the adequacy of the existing monitoring well network, and provide recommendations for monitoring well augmentation, as necessary.

2. Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant East BAP.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The East BAP CCR unit is located at the north end of the Plant and approximately 2,000 feet north-northwest of Brandy Branch Reservoir (**Figures 1** and **2**).

2.2 Description of East BAP CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the East BAP.

2.2.1 Embankment Configuration

The East BAP is partially incised into native soils with an embankment height of approximately 4 feet (AMEC, 2011). The East BAP embankments are constructed of compacted clay on a 3:1 slope (3 feet horizontal, 1 foot vertical) (Sargent & Lundy, 1983). The elevation of the top of the embankment around the perimeter of the East BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, May 2011). The interior bottom elevation of the East BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Johnson & Pace, June 2011).

2.2.2 Area/Volume

The East BAP is approximately 31.5 acres in size. The design maximum ash storage capacity of the East BAP is 188 acre feet (Sargent & Lundy, 1983). Johnson & Pace calculated the East BAP ash storage capacity in 2011 at 161 acre feet at an elevation of 355 feet amsl (maximum operating level) (Johnson & Pace, June 2011).

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, flue gas desulfurization sludge) have been generated. The East BAP, which was placed into operation in 1985, receives bottom ash and economizer ash sluiced from the power plant boiler (**Figure 3**). Clear water overflow from the East BAP discharges into the Clearwater Pond located directly south of the East BAP. Bottom ash and economizer ash are periodically excavated from the East BAP and hauled by truck to either the on-site landfill for disposal, or sold for offsite beneficial re-use.

The base of the East BAP was constructed in 1983 with a compacted clay liner (Sargent & Lundy, 1983). Following installation of the compacted clay liner, soil borings S-4 through S-7 were advanced below the base of the East BAP to total depths of six feet in September 1983 (Southwestern Laboratories, 1984). The lithologic data from soil borings S-4 through S-7 confirm at least six feet of clay is present below the base of the East BAP (Sargent & Lundy, 1984).

2.2.4 Surface Water Control

Surface water elevation in the East BAP is controlled by a weir box and a manually operated gate valve on a 36-inch-diameter discharge pipe at the southwest corner of the pond. Clear water overflow from the East BAP discharges through the 36-inch-diameter pipe into the 2.7- acre Clearwater Pond located directly south of the East BAP (**Figure 3**). Water in the Clearwater Pond is pumped (re-circulated) back into the boiler ash hopper.

2.3 Previous Investigations

The initial soils investigation and design of the East BAP was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, and design of the East BAP. As discussed above in Section 2.2.3, the design included installation of a clay liner below the East BAP.

In September-October 1983, Southwestern Laboratories conducted a soil investigation at the Plant, including advancement of four soil borings (S-4 through S-7) below the East BAP (Southwestern Laboratories, 1984).

In 1984, Sargent & Lundy conducted an evaluation of the East BAP. This report included evaluation of soil sample geotechnical data, and concluded a low-permeability clay liner was present below the East BAP (Sargent & Lundy, 1984).

In 2009, ETTL Engineers & Consultants (ETTL) conducted a geotechnical investigation of the East BAP earthen embankment. The investigation included installation of two soil borings through the embankment (E1, E2), completion of the soil borings as piezometers PE-1 and PE-2, respectively, and collection of soil samples for geotechnical analyses. The report concluded the embankment was stable and the existing embankment slopes were acceptable if conditions are maintained (ETTL, 2010). The conditions to be maintained included embankment protection from erosion (vegetative cover), removal of brush and trees two feet or more in height, and control of animal burrowing.

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, 2011).

In 2011, Johnson & Pace performed a hydraulic analysis of the East BAP for a 10-year, 24-hour rainfall event in accordance with the TCEQ TPDES permit design criteria. The report concluded the storage capacity of the East BAP is hydraulically adequate (Johnson & Pace, May 2011).

In December 2015, Auckland Consulting further expanded the groundwater monitoring well system at the Plant, including installation of six monitoring wells (AD-30 through AD-35) (Auckland Consulting, 2016).

2.4 Hydrogeologic Setting

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Plant. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of approximately 100 feet (Broom, 1966).

These features are further illustrated on five lines of cross section that were prepared through the East BAP area, with three lines trending from west to east (A-A'; B-B'; C-C'), and the other two lines trending from north to south (D-D'; E-E'). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure 4** (A-A') through **Figure 8** (E-E').

2.4.1 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1° Fahrenheit (F) in January to 83.8°F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.2 Regional and Local Geologic Setting

The central and northern portions of the Plant, including the East BAP, are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 "*Ground-Water Resources of Harrison County, Texas*" (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology "*Geologic Atlas of Texas – Tyler Sheet*" (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K "*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*" (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled "*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*" (ETTL, 2010).

2.4.3 Surface Water and Surface Water Groundwater Interactions

Figure 9 is a potentiometric surface map based on January 2016 water level data for the uppermost water bearing unit at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1**. As shown on **Figure 9**, shallow groundwater flow direction in the area of the East BAP is west-southwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The East BAP is located approximately 2,000 feet north-northwest of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980's. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figure 9**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore shallow groundwater in the area of the East BAP does not discharge into Brandy Branch Reservoir.

2.4.4 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled approximately 500 feet south (side gradient) of the East BAP in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 350 to 430 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled approximately ¼-mile southwest (downgradient) of the East BAP for NFR Energy in 2008 for use as a rig supply well. The water well was screened from 250 to 310 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth, and is located approximately ¼-mile east (up gradient) of the Pirkey Power Plant.

3. Groundwater Monitoring Well Network Evaluation

The existing monitoring well network present at the Site was evaluated to determine if any of the wells were viable for continued use as part of the groundwater monitoring well network or also retained as part of a larger groundwater hydraulic monitoring well network. The hydrogeologic conditions were also evaluated to determine if the uppermost aquifer unit has an effective well network. The evaluation was completed in accordance with 40 CFR 257.91 to have an established monitoring well network that effectively monitors the uppermost aquifer up gradient and down gradient of the Site. The up gradient wells represent background groundwater quality and the down gradient wells are to be placed down gradient of the CCR unit boundary to monitor water quality.

3.1 Hydrostratigraphic Units

3.1.1 Horizontal and Vertical Position Relative to CCR Unit

Geologic data from soil borings, piezometers, and monitoring wells installed at the Site show the uppermost aquifer in the area of the East BAP is a very fine to fine grained clayey and silty sand stratum with an average thickness of approximately 15 feet that is located between an elevation of approximately 325 and 340 feet amsl (**Appendix A**). The base of the East BAP is at an elevation of 347 feet amsl. Therefore the separation distance between the uppermost aquifer and the base of the East BAP is approximately seven feet. This separation distance is further illustrated on cross section A-A' (**Figure 4)** and cross section E-E' (**Figure 8)**.

3.1.2 Overall Flow Conditions

Groundwater is recharged from regional precipitation infiltration. The uppermost aquifer (clayey and silty sand) is expected to have a hydraulic conductivity of approximately 10^{-4} centimeters per second (Fetter, 1980). Based on the hydraulic conductivity and saturated thickness (approximately 15 feet), the yield of the uppermost aqufier is anticipated to exceed the TCEQ non-useable (Class 3) limit of 150 gallons per day (TCEQ, 2010).

Available groundwater elevations are summarized on **Table 1** for 2011 through 2016. The most recent comprehensive groundwater data set from January 20, 2016 is depicted on **Figure 9**. The groundwater flow is west-southwesterly towards Hatley Creek, which is located approximately one mile west of the Site.

3.2 Uppermost Aquifer

3.2.1 CCR Rule Definition

Per 40 CFR 257.60(a), new CCR landfills, existing and new CCR surface impoundments, and all lateral expansions of CCR units must be constructed with a base that is located no less than 1.52 meters (five ft) above the upper limit of the uppermost aquifer, or must demonstrate there will not be an intermittent, recurring, or sustained hydraulic connection between any portion of the base of the CCR unit and the uppermost aquifer due to normal fluctuations in groundwater elevations (including the seasonal high conditions).

The CCR rule definitions for an aquifer and the uppermost aquifer as specified in 40 CFR 257.53 indicates an aquifer is a geologic formation capable of yielding usable quantities of groundwater to wells or springs while an uppermost aquifer is defined as the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers, that are hydraulically interconnected with this aquifer within the facility's property boundary. Upper limit is measured at a point nearest to the natural groundwater surface to which the aquifer rises during the wet season.

3.2.1.1 Common Definitions

An aquifer is commonly defined as a geologic unit that stores and transmits water (readily or at sufficient flow rates) to supply wells and springs (USGS, 2015; Fetter, 2001). The uppermost aquifer is considered the first encountered aquifer nearest to the CCR unit.

3.2.2 Identified Onsite Hydrostratigraphic Unit

The identified Site hydrostratigraphic unit in the area of the East BAP is the clayey and silty sand stratum that is located between an elevation of approximately 325 and 340 feet amsl.

3.3 Review of Existing Monitoring Well Network

3.3.1 Overview

The Site was visited by ARCADIS and AEP personnel on August 19, 2015 to review existing well network conditions and locations. A well construction table that summarizes the location, ground surface elevation, borehole depth, installation date, and associated well construction details of the monitoring well network is included as

Table 2. Photo documentation of the located wells during the August 19, 2015 site visit is provided in **Appendix B**.

Monitoring wells AD-2, AD-3, AD-4, AD-12, and AD-18 were previously installed at the Site to monitor the uppermost aquifer (clayey and silty sand stratum) associated with the East BAP. As discussed above in Section 3.1.1, the uppermost aquifer below the East BAP is approximately 15 feet thick and is located between an elevation of approximately 325 and 340 feet amsl.

3.3.2 Gaps in Monitoring Network

As shown on Geologic Cross Section A-A' (**Figure 4**), existing monitoring well AD-4 is screened in the uppermost aquifer upgradient (east) of the East BAP, and existing monitoring well AD-3 is screened in the uppermost aquifer sidegradient (northwest) of the East BAP. Existing monitoring wells AD-4, AD-12 and AD-18 (also located east of the East BAP) will be utilized as upgradient monitoring wells for the East BAP. Existing monitoring well AD-2, located west-southwest of the East BAP, will be utilized as a downgradient monitoring well for the East BAP.

As shown on **Figure 9**, shallow groundwater flow direction in the area of the East BAP is west-southwesterly. One existing monitoring well (AD-2) was located hydraulically downgradient of the East BAP during the August 19, 2015 site visit, and three downgradient monitoring wells are required to monitor groundwater quality downgradient of a CCR unit. This data gap was addressed by installation of new downgradient monitoring wells AD-31 and AD-32 during December 2015 as shown on **Figure 9** and **10**. With the addition of monitoring wells AD-31 on the west side of the East BAP and AD-32 on the south central side of the East BAP, there are no gaps remaining in the groundwater monitoring network for the East BAP.

4. Recommended Monitoring Network and PE Certification

The recommended existing groundwater monitoring well network is intended to meet specifications stated in 40 CFR 257.91. Recommended wells are further discussed with respect to location to the East BAP (up gradient or down gradient), well depth, and well construction. The recommended network would provide an improved understanding of groundwater quality, hydraulics, and groundwater flow at the East BAP.

4.1 Recommended Monitoring Well Network Distribution

Three up gradient well locations (existing monitoring wells AD-4, AD-12, and AD-18) and three down gradient well locations (existing monitoring wells AD-2, AD-31, and AD-32) are recommended to establish a groundwater quality monitoring well network for the East BAP. In addition, existing sidegradient monitoring well AD-3 may be utilized as a piezometer to obtain additional groundwater flow direction and gradient data for the East BAP.

4.1.1 Location

The recommended monitoring well network for groundwater quality of the uppermost aquifer at the East BAP is summarized on **Table 3** and illustrated on **Figure 10.**

4.1.2 Depth

The screen depths for the monitoring wells recommended for inclusion in the monitoring network are within the shallow saturated sand stratum (uppermost aquifer) that occurs between an elevation of approximately 325 and 340 feet amsl as shown on Geologic Cross Sections A-A' (**Figure 4**) and E-E' (**Figure 8**). The screen elevations are presented in **Table 3**.

4.1.3 Well Construction

As discussed above in Section 3.3.2, the gap in the monitoring well network for the uppermost aquifer at the East BAP was addressed by installation of monitoring wells AD-31 and AD-32 during December 2015. Monitoring wells AD-31 and AD-32 were installed by a Texas Department of Licensing and Regulation (TDLR)-licensed water well driller. Well construction data for the monitoring well network are summarized on **Tables 2** and **3**, and the monitoring well completion diagrams are provided in **Appendix A**.

4.2 Professional Engineer's Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, the proposed groundwater monitoring system will be adequate to meet the requirements of 40 CFR Part 257.91.

Acronyms and Abbreviations:
NA = Data not available
ft = feet
bls = below land surface
msl = mean sea level

Table 3
Proposed Well Network
AEP Pirkey Power Plant - East Bottom Ash Pond
Hallsville, Harrison County, Texas

Well ID	Exisiting/ Proposed	Hydrostratigraphic Unit Target	Location Description		Screen Top Target Elevation[a] (ft amsl)	Screen Bottom Target Elevation[a] (ft amsl)	Screen Length (ft)	Comments
Upgradient								
AD-4	Exisiting	Uppermost Water-Bearing Unit	East of East Bottom Ash Pond	Upgradient	337.7	317.7	20	Existing well installed in 1983; well will be utilitzed to establish backgroud water quality
AD-12	Exisiting	Uppermost Water-Bearing Unit	Northeast of Stack Out Area	Upgradient	347.8	327.8	20	Existing well installed in 1986; well will be utilitzed to establish backgroud water quality
AD-18	Exisiting	Uppermost Water-Bearing Unit	East of East Bottom Ash Pond	Upgradient	345.5	335.5	10	Existing well installed in 2011; well will be utilitzed to establish backgroud water quality
Downgradient								
AD-2	Existing	Uppermost Water-Bearing Unit	West-Southwest of East Bottom Ash Pond	Down gradient	321.3	301.3	20	Existing well installed in 1983; uppermost shallow aquifer adjacent to the East Bottom Ash Pond - downgradient
AD-31	Existing	Uppermost Water-Bearing Unit	West of East Bottom Ash Pond	Down gradient	337.8	322.8	15	New monitoring well installed during December 2015 in uppermost shallow aquifer adjacent to the East Bottom Ash Pond - downgradient
AD-32	Existing	Uppermost Water-Bearing Unit	South of East Bottom Ash Pond	Down gradient	344.2	324.2	20	New monitoring well installed during December 2015 in uppermost shallow aquifer adjacent to the East Bottom Ash Pond - downgradient
Piezometers								
AD-3	Exisiting	Uppermost Water-Bearing Unit	Northwest of East Bottom Ash Pond	Side gradient	335.8	315.8	20	Existing well installed in 2011; and utilitzed to obtain water level data for uppermost water-bearing unit

Footnotes:

a. Target elevations are an estimated range.

Acronyms and Abbreviations:

U=Upgradient
D=Downgradient
ft = feet
amsl = above mean sea level

TDS	total dissolved solids

1. Objective

This report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to assess the adequacy of the groundwater monitoring well network included in the Coal Combustion Residual (CCR) requirements, as specified in Code of Federal Regulations (CFR) 40 CFR 257.91, for the West Bottom Ash Pond (BAP) CCR Unit at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The CCR requirements include an evaluation of the adequacy of the groundwater monitoring well network to characterize groundwater quality up and down gradient of the CCR unit and an evaluation of whether the CCR unit meets up to 5 location restrictions, which include: the base of the CCR unit is 5 feet (ft) above and isolated from the uppermost aquifer, the CCR unit may not be located in a wetland, within 200 ft of the damage zone of a fault that has displacement during the Holocene, within a seismic impact zone, or in an unstable area.

Four regulated CCR units associated with the Plant were identified for review, which include the West BAP, East BAP, Stack Out Area, and Landfill (**Figure 2**). This report summarizes the evaluation of the groundwater monitoring well network in the uppermost aquifer at the West BAP (Site). The evaluation of the location restriction criteria is not included in this report and will be completed under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the West BAP CCR unit, as well as publically-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on all documents reviewed and will further describe the uppermost aquifer, include an evaluation of the adequacy of the existing monitoring well network, and provide recommendations for monitoring well augmentation, as necessary.

2. Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant West BAP.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The West BAP CCR unit is located at the north end of the Plant and approximately 3,000 feet northwest of Brandy Branch Reservoir (**Figures 1** and **2**).

2.2 Description of West BAP CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the West BAP.

2.2.1 Embankment Configuration

The West BAP embankments have a maximum height of approximately 25 feet and are constructed of compacted clay on a slope ranging from 2.5:1 (2.5 feet horizontal, 1 foot vertical) to 3:1 (Sargent & Lundy, 1983). The elevation at the top of the embankment around the perimeter of the West BAP is approximately 357 feet amsl, and the normal operating level is approximately 354 feet amsl (Johnson & Pace, 2011). The interior bottom elevation of the West BAP is approximately 347 feet amsl (Sargent & Lundy, 1983; Akron Consulting, 2012).

2.2.2 Area/Volume

The West BAP is approximately 30.9 acres in size. The design maximum ash storage capacity of the West BAP is 188 acre feet at an elevation of 354 feet amsl (normal operating level) and 216.5 acre feet at an elevation of 355 feet amsl (maximum operating level) (Sargent & Lundy, 1983; Akron Consulting, 2012).

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, flue gas desulfurization sludge) have been generated. The West BAP, which was placed into operation in 1985, receives bottom ash and economizer ash sluiced from the power plant boiler (**Figure 3**). Clear water overflow from the West BAP discharges into the Clearwater Pond located southeast of the West BAP. Bottom ash and economizer ash are periodically excavated from the West BAP and hauled by truck to either the on-site landfill for disposal, or sold for offsite beneficial re-use.

The base of the West BAP was constructed in 1983 with a compacted clay liner (Sargent & Lundy, 1983). Following installation of the compacted clay liner, soil borings S-8 through S-11 were advanced below the base of the West BAP to total depths of six feet in September 1983 (Southwestern Laboratories, 1984). The lithologic data from soil borings S-8 through S-11 confirm at least six feet of clay is present below the base of the West BAP (Sargent & Lundy, 1984).

2.2.4 Surface Water Control

Surface water elevation in the West BAP is controlled by a weir box and a manually operated gate valve on a 36-inch-diameter discharge pipe at the southeast corner of the pond. Clear water overflow from the West BAP discharges through the 36-inch-diameter pipe into the 2.7-acre Clearwater Pond located southeast of the West BAP (Figure 3). Water in the Clearwater Pond is pumped (re-circulated) back into the boiler ash hopper.

2.3 Previous Investigations

The initial soils investigation and design of the West BAP was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, and design of the West BAP. As discussed above in Section 2.2.3, the design included installation of a clay liner below the West BAP.

In September-October 1983, Southwestern Laboratories conducted a soil investigation at the Plant, including advancement of four soil borings (S-8 through S-11) below the West BAP (Southwestern Laboratories, 1984).

In 1984, Sargent & Lundy conducted an evaluation of the West BAP. This report included evaluation of soil sample geotechnical data, and concluded a low-permeability clay liner was present below the West BAP (Sargent & Lundy, 1984).

In 2009, ETTL Engineers & Consultants (ETTL) conducted a geotechnical investigation of the West BAP earthen embankment. The investigation included installation of two soil borings through the embankment (W1, W3) and two soil borings along the outer toe of the embankment (W2, W4), completion of soil borings W1 and W3 as piezometers PW-1 and PW-3, respectively, and collection of soil samples for geotechnical analyses. The report concluded the embankment was stable and the existing embankment slopes were acceptable if conditions are maintained (ETTL, 2010). The conditions to be maintained included embankment protection from erosion (vegetative cover), removal of brush and trees two feet or more in height, and control of animal burrowing.

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, 2011).

In 2011, Johnson & Pace performed a hydraulic analysis of the West BAP for a 10-year, 24-hour rainfall event in accordance with the TCEQ TPDES permit design criteria. The report concluded the storage capacity of the West BAP is hydraulically adequate (Johnson & Pace, 2011).

In December 2015, Auckland Consulting further expanded the groundwater monitoring well system at the Plant, including installation of six monitoring wells (AD-30 through AD-35) (Auckland Consulting, 2016).

2.4 Hydrogeologic Setting

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Plant. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of approximately 100 feet (Broom, 1966).

These features are further illustrated on five lines of cross section that were prepared through the West BAP area, with three lines trending from west to east (A-A'; B-B'; C-C'), and the other two lines trending from north to south (D-D'; E-E'). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure 4** (A-A') through **Figure 8** (E-E').

2.4.1 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1° Fahrenheit (F) in January to 83.8°F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.2 Regional and Local Geologic Setting

The central and northern portions of the Plant, including the West BAP, are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 "*Ground-Water Resources of Harrison County, Texas*" (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology "*Geologic Atlas of Texas – Tyler Sheet*" (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K "*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*" (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled "*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*" (ETTL, 2010).

2.4.3 Surface Water and Surface Water Groundwater Interactions

Figure 9 is a potentiometric surface map based on January 2016 water level data for the uppermost water bearing unit at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1**. As shown on **Figure 9**, shallow groundwater flow direction in the area of the West BAP is west-southwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The West BAP is located approximately 3,000 feet northwest of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980's. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figure 9**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore shallow groundwater in the area of the West BAP does not discharge into Brandy Branch Reservoir.

2.4.4 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled approximately 500 feet southeast (side gradient) of the West BAP in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 350 to 430 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled approximately ¼-mile south (side gradient) of the West BAP for NFR Energy in 2008 for use as a rig supply well. The water well was screened from 250 to 310 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth, and is located approximately ¼-mile east (up gradient) of the Pirkey Power Plant.

3. Groundwater Monitoring Well Network Evaluation

The existing monitoring well network present at the Site was evaluated to determine if any of the wells were viable for continued use as part of the groundwater monitoring well network or also retained as part of a larger groundwater hydraulic monitoring well network. The hydrogeologic conditions were also evaluated to determine if the uppermost aquifer unit has an effective well network. The evaluation was completed in accordance with 40 CFR 257.91 to have an established monitoring well network that effectively monitors the uppermost aquifer up gradient and down gradient of the Site. The up gradient wells represent background groundwater quality and the down gradient wells are to be located down gradient of the CCR unit boundary to monitor water quality.

3.1 Hydrostratigraphic Units

3.1.1 Horizontal and Vertical Position Relative to CCR Unit

Geologic data from soil borings, piezometers, and monitoring wells installed at the Site show the uppermost aquifer in the area of the West BAP is a very fine to fine grained clayey and silty sand stratum with an average thickness of approximately 15 feet that is located between an elevation of approximately 325 and 340 feet amsl (**Appendix A**). The base of the West BAP is at an elevation of 347 feet amsl. Therefore the separation distance between the uppermost aquifer and the base of the West BAP is approximately seven feet. This separation distance is further illustrated on cross section A-A' (**Figure 4)** and cross section D-D' (**Figure 7)**.

3.1.2 Overall Flow Conditions

Groundwater is recharged from regional precipitation infiltration. The uppermost aquifer (clayey and silty sand) is expected to have a hydraulic conductivity of approximately 10^{-4} centimeters per second (Fetter, 1980). Based on the hydraulic conductivity and saturated thickness (approximately 15 feet), the yield of the uppermost aquifer is anticipated to exceed the TCEQ non-useable (Class 3) limit of 150 gallons per day (TCEQ, 2010).

Available groundwater elevations are summarized on **Table 1** for 2011 through 2016. The most recent comprehensive groundwater data set from January 20, 2016 is depicted on **Figure 9**. The groundwater flow is west-southwesterly towards Hatley Creek, which is located approximately one mile west of the Site.

3.2 Uppermost Aquifer

3.2.1 CCR Rule Definition

Per 40 CFR 257.60(a), new CCR landfills, existing and new CCR surface impoundments, and all lateral expansions of CCR units must be constructed with a base that is located no less than 1.52 meters (five ft) above the upper limit of the uppermost aquifer, or must demonstrate there will not be an intermittent, recurring, or sustained hydraulic connection between any portion of the base of the CCR unit and the uppermost aquifer due to normal fluctuations in groundwater elevations (including the seasonal high conditions).

The CCR rule definitions for an aquifer and the uppermost aquifer as specified in 40 CFR 257.53 indicates an aquifer is a geologic formation capable of yielding usable quantities of groundwater to wells or springs while an uppermost aquifer is defined as the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers, that are hydraulically interconnected with this aquifer within the facility's property boundary. Upper limit is measured at a point nearest to the natural groundwater surface to which the aquifer rises during the wet season.

3.2.1.1 Common Definitions

An aquifer is commonly defined as a geologic unit that stores and transmits water (readily or at sufficient flow rates) to supply wells and springs (USGS, 2015; Fetter, 2001). The uppermost aquifer is considered the first encountered aquifer nearest to the CCR unit.

3.2.2 Identified Onsite Hydrostratigraphic Unit

The identified Site hydrostratigraphic unit in the area of the West BAP is the clayey and silty sand stratum that is located between an elevation of approximately 325 and 340 feet amsl.

3.3 Review of Existing Monitoring Well Network

3.3.1 Overview

The Site was visited by ARCADIS and AEP personnel on August 19, 2015 to review existing well network conditions and locations. A well construction table that summarizes the location, ground surface elevation, borehole depth, installation date, and associated well construction details of the monitoring well network is included as **Table 2**. Photo documentation of the located wells during the August 19, 2015 site visit is provided in **Appendix B**.

Monitoring wells AD-3, AD-12, AD-17, AD-18, AD-28, and AD-29 were previously installed at the Site to monitor the uppermost aquifer (clayey and silty sand stratum) associated with the West BAP. As discussed above in Section 3.1.1, the uppermost aquifer below the West BAP is approximately 15 feet thick and is located between an elevation of approximately 325 and 340 feet amsl.

3.3.2 Gaps in Monitoring Network

As shown on Geologic Cross Section A-A' (**Figure 4**), existing monitoring well AD-3 is screened in the uppermost aquifer upgradient (east) of the West BAP, and existing monitoring well AD-17 is screened in the uppermost aquifer downgradient (west) of the West BAP. Existing monitoring wells AD-3, AD-12 and AD-18 (also located east of the West BAP) will be utilized as upgradient monitoring wells for the West BAP. Existing monitoring wells AD-17 and AD-28 (also located west of the West BAP) will be utilized as downgradient monitoring wells for the West BAP.

As shown on **Figure 9**, shallow groundwater flow direction in the area of the West BAP is west-southwesterly. Two existing monitoring wells (AD-17, AD-28) were located hydraulically downgradient of the West BAP during the August 19, 2015 site visit, and three downgradient monitoring wells are required to monitor groundwater quality downgradient of a CCR unit. This data gap was addressed by installation of new downgradient monitoring well AD-30 along the south central side of the West BAP during December 2015 as shown on **Figure 9** and **10**. With the addition of monitoring well AD-30, there are no gaps remaining in the groundwater monitoring network for the West BAP.

4. Recommended Monitoring Network and PE Certification

The recommended existing groundwater monitoring well network is intended to meet specifications stated in 40 CFR 257.91. Recommended wells are further discussed with respect to location to the West BAP (up gradient or down gradient), well depth, and well construction. The recommended network would provide an improved understanding of groundwater quality, hydraulics, and groundwater flow at the West BAP.

4.1 Recommended Monitoring Well Network Distribution

Three up gradient well locations (existing monitoring wells AD-3, AD-12, and AD-18) and three down gradient well locations (existing monitoring wells AD-17, AD-28, and AD-30) are recommended to establish a groundwater quality monitoring well network for the West BAP. In addition, existing side gradient monitoring well AD-29 may be utilized as a piezometer to obtain additional groundwater flow direction and gradient data for the West BAP.

4.1.1 Location

The recommended monitoring well network for groundwater quality of the uppermost aquifer at the West BAP is summarized on **Table 3** and illustrated on **Figure 10.**

4.1.2 Depth

The screen depths for the monitoring wells recommended for inclusion in the monitoring well network are within the shallow saturated sand stratum (uppermost aquifer) that occurs between an elevation of approximately 325 and 340 feet amsl as shown on Geologic Cross Sections A-A' (**Figure 4**) and D-D' (**Figure 7**). The screen elevations are presented in **Table 3**.

4.1.3 Well Construction

As discussed above in Section 3.3.2, the gap in the monitoring well network for the uppermost aquifer at the West BAP was addressed by installation of monitoring well AD-30 during December 2015. Monitoring well AD-30 was installed by a Texas Department of Licensing and Regulation (TDLR)-licensed water well driller. Well construction data for the monitoring well network are summarized on **Tables 2** and **3**, and the monitoring well completion diagrams are provided in **Appendix A**.

4.2 Professional Engineer's Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, the proposed groundwater monitoring system will be adequate to meet the requirements of 40 CFR Part 257.91.

Acronyms and Abbreviations:
NA = Data not available
ft = feet
bls = below land surface
msl = mean sea level

Table 3
Proposed Well Network
AEP Pirkey Power Plant - West Bottom Ash Pond
Hallsville, Harrison County, Texas

Well ID	Exisiting/ Proposed	Hydrostratigraphic Unit Target	Location Description		Screen Top Target Elevation[a] (ft amsl)	Screen Bottom Target Elevation[a] (ft amsl)	Screen Length (ft)	Comments
Upgradient								
AD-3	Exisiting	Uppermost Water-Bearing Unit	East of West Bottom Ash Pond	Upgradient	335.8	315.8	20	Existing well installed in 1983; well will be utilitzed to establish backgroud water quality
AD-12	Exisiting	Uppermost Water-Bearing Unit	Northeast of Stack Out Area	Upgradient	347.8	327.8	20	Existing well installed in 1986; well will be utilitzed to establish backgroud water quality
AD-18	Exisiting	Uppermost Water-Bearing Unit	East of West Bottom Ash Pond	Upgradient	345.5	335.5	10	Existing well installed in 2011; well will be utilitzed to establish backgroud water quality
Downgradient								
AD-17	Existing	Uppermost Water-Bearing Unit	West of West Bottom Ash Pond	Down gradient	332.7	312.7	20	Existing well installed in 2010; uppermost shallow aquifer adjacent to the West Bottom Ash Pond - downgradient
AD-28	Existing	Uppermost Water-Bearing Unit	Southwest of West Bottom Ash Pond	Down gradient	320.9	300.9	20	Existing well installed in 2010; uppermost shallow aquifer adjacent to the West Bottom Ash Pond - downgradient
AD-30	Existing	Uppermost Water-Bearing Unit	South of West Bottom Ash Pond	Down gradient	329.0	314.0	15	New monitoring well installed during December 2015 in uppermost shallow aquifer adjacent to the West Bottom Ash Pond - downgradient
Piezometers								
AD-29	Exisiting	Uppermost Water-Bearing Unit	North of West Bottom Ash Pond	Side gradient	340.2	320.2	20	Existing well installed in 2011; and utilitzed to obtain water level data for uppermost water-bearing unit

Footnotes:
a. Target elevations are an estimated range.

Acronyms and Abbreviations:
U=Upgradient
D=Downgradient
ft = feet
amsl = above mean sea level

1 Objective

This update report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to provide an updated assessment the adequacy of the groundwater monitoring well network included in the Coal Combustion Residual (CCR) requirements, as specified in Code of Federal Regulations (CFR) 40 CFR 257.91 and Texas Administrative Code (TAC) 30 TAC 352.911, for the Landfill CCR Unit at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The Landfill CCR Unit at the Plant was 130 acres and when fully expanded will cover approximately 145 acres in size. As shown on **Figure 2**, the Landfill was expanded laterally to the south beginning in 2018 (2018 Lateral Expansion). The 2018 Lateral Expansion will be approximately 15 acres in size. Currently approximately 3.5 acres of the 2018 landfill expansion has been constructed, in the northern portion of the expansion area, including the basal liners and leachate drainage system. The remaining area of the 2018 landfill expansion has not yet been fully constructed**.** During Lateral Expansion construction activities one of the existing downgradient monitoring wells (monitoring well AD-35) was plugged and replaced with new monitoring well AD-36. Monitoring well AD-35 was plugged because it was located within the footprint of the 2018 Lateral Expansion, and newly installed monitoring well AD-36 is located hydraulically downgradient of the 2018 Lateral Expansion.

Four regulated CCR units associated with the Plant were identified for review, which include the West BAP, East BAP, Stack Out Area, and Landfill (**Figure 2**). This report provides an updated evaluation of the groundwater monitoring well network in the uppermost aquifer at the Landfill, including the 2018 Lateral Expansion. The updated evaluation of the location restriction criteria for the Landfill 2018 Lateral Expansion is not included in this report and was completed previously under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the Landfill CCR unit, including the 2018 Lateral Expansion area, as well as publicly-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on all documents reviewed and will further describe the uppermost aquifer, include an evaluation of the adequacy of the existing monitoring well network, and provide recommendations for monitoring well augmentation, as necessary.

2 Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant Landfill.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The existing Landfill CCR unit is located in the southern portion of the Plant. The existing Landfill CCR unit is currently approximately 133.5 acres in size, including 3.5 acres associated with the 2018 Landfill Lateral Expansion. When completed, the 2018 Landfill Lateral Expansion will cover in approximately 15 acres directly south of the existing Landfill (**Figures 2** and **3**).

2.2 Description of Landfill CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the Landfill.

2.2.1 Embankment Configuration

The Landfill was constructed in the southwestern portion of the Plant, and as shown on the U.S. Geological Survey 1983 topographic map (**Figure 1**), the southwestern portion of the Plant contained an unnamed intermittent tributary of Hatley Creek prior to Landfill construction in 1984. The Landfill was constructed within the unnamed tributary creek which had a bottom elevation ranging from approximately 290 feet amsl on the south side of the Landfill to 300 feet amsl on the north side of the Landfill. The native soil sidewalls of the tributary creek at the Landfill location have a maximum elevation of approximately 355 feet amsl. Therefore, as shown on Geologic Cross Section C-C’ (**Figure 6**), the Landfill is partially incised within the tributary creek, and the tributary creek native soil sidewalls serve as a natural embankment for the lower portion of the Landfill.

The original Landfill design included emplacement of CCR materials in the Landfill with 3:1 slopes (3 feet horizontal, 1 foot vertical) with an approximate 10 foot wide bench for every 20 foot vertical rise of CCR material (VFL Technology Corporation, 1984). In addition to the Landfill CCR material embankments, earthen embankments are present around portions of the Landfill to control storm water flow.

The 2018 Landfill Lateral Expansion will cover approximately 15 acres directly south of the existing Landfill. Currently approximately 3.5 acres of the 2018 landfill expansion has been constructed, in the northern portion of the expansion area, including the basal liners and leachate drainage system. The remaining area of the 2018 landfill expansion has not yet been constructed**.** In 2016, Auckland Consulting conducted a stability assessment of the 2018 Lateral Expansion area and concluded the embankments would be stable on slopes no steeper than 3:1 (Auckland, November 2016). The 2016 Auckland Consulting report stated the northern and eastern extents of the 2018 Lateral Expansion will be constructed contiguous to the existing Landfill disposal area, and ash disposal will be completed in multiple lifts, each with an approximate height of 20 feet, integrated with safety benches, and maximum side slopes of 3:1 to a maximum waste height of 120 feet.

2.2.2 Area/Volume

Prior to expansion, the landfill was approximately 130 acres in size and was designed to receive 12,207,000 cubic yards (7,566 acre feet) of CCR materials including fly ash, bottom ash, economizer ash, and stabilized FGD sludge (VFL Technology Corporation, 1984). The design capacity of the CCR materials to be placed within the 2018 Lateral Expansion is approximately 2,200,000 cubic yards.

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, stabilized FGD sludge) have been generated. The CCR materials that are not taken offsite for beneficial reuse are disposed of in the Landfill. The Landfill was constructed in several phases beginning with the northeast portion (Phase 1) in 1984. The Landfill was expanded (east-central portion) in 1985 and 1987. The Landfill was subsequently expanded to the west and south during the 1990’s, including construction of the Landfill Stormwater Runoff Pond (non-CCR unit) directly south of the Landfill in 1993 and 1994.

In 2005, ETTL conducted a geotechnical evaluation of the Landfill and Landfill Stormwater Runoff Pond, including installation 30 soil borings, ten cone penetration test (CPT) borings, and geotechnical testing of soil samples. The Landfill was further expanded to the west between 2005 and 2015 to its previous size of approximately 130 acres as shown on **Figure 3**.

The 2018 Landfill Lateral Expansion design included emplacement of up to 120 feet of CCR materials with maximum side slopes of 3:1 above the Landfill liner system which consisted of a 60-mil HDPE top liner underlain by a 2-foot-thick compacted clay bottom liner. Prior to installation of the liner system, approximately 10 to 15 feet of cut into the existing soils will occur along the topographically higher southern portion of the Lateral Expansion, and emplacement of these soils (clayey sands, silty clayey sand and/or lean clays) as fill materials below the liner system in the topographically lower central and northern portions of the Lateral Expansion. As detailed below in Section 3.3.2, during Lateral Expansion construction activities, existing downgradient monitoring well AD-35, located within the Lateral Expansion construction zone, was plugged and replaced with new monitoring well (AD-36) located directly downgradient to the west of the Lateral Expansion area.

2.2.4 Surface Water Control

Surface water in the area of the existing Landfill flows in a general southerly direction to the Landfill Stormwater Runoff Pond located directly southwest of the existing Landfill. Surface water in the area of the 2018 Landfill Lateral Expansion flows in a general westerly direction to the Landfill Stormwater Runoff Pond. The Landfill Stormwater Runoff Pond, which is approximately 16 acres in size, also receives (1) Landfill leachate that is gravity drained from the existing Landfill via underground lateral perforated pipes and permeable bottom ash materials that were installed above portions of the existing Landfill liner, (2) Landfill leachate that will gravity drain via underground lateral perforated pipes that were installed above the 2018 Landfill Lateral Expansion liner system, and (3) shallow groundwater that will gravity drain via underground lateral perforated HDPE underdrain pipes that were installed in permeable bottom ash materials approximately seven feet below the 60-mil HDPE liner of the 2018 Landfill Lateral Expansion.

2.3 Previous Investigations

The initial soils investigation and design of the Plant was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, including the Landfill Area.

A soils investigation of the Landfill was conducted by Southwestern Laboratories in 1984. The investigation included installation of 45 soil borings and geotechnical analyses of soil samples. The report recommended installation of three feet of compacted clay as the bottom liner for the Landfill (Southwestern Laboratories, July 1984).

An engineering design report for the Landfill was prepared by VFL Technology Corporation in 1984. The Landfill design included a bottom compacted clay liner three feet in thickness, and Landfill side slopes of 3:1 (VFL Technology Corporation, 1984).

In 1985, Southwestern Laboratories conducted a geotechnical evaluation of the clay liner that was installed at the base of the Landfill, including installation of four soil borings and permeability testing of soil samples. The report concluded the clay liner was three feet thick with a permeability less than 1×10^{-7} centimeters per second (cm/sec) (Southwestern Laboratories, 1985).

In 1993, Alliance Inc. conducted a geotechnical investigation of the clay liner installed at the base of the Landfill following a Landfill expansion phase in 1993. The report concluded the clay liner was three feet or more in thickness, and the clay liner met the permeability specifications of $<1 \times 10^{-7}$ cm/sec (Alliance Inc., 1993).

In 1995, Central and South West Services prepared design specifications for Landfill expansion to the west and south. The design specifications included a geosynthetic clay liner overlain by a 0.060-inch (60 mil) HDPE liner (Central and South West Services, 1995).

In 2005, ETTL conducted a geotechnical evaluation of the Landfill and Landfill Stormwater Runoff Pond, including installation 30 soil borings, ten CPT borings, and geotechnical testing of soil samples. The geotechnical data was obtained to design Landfill expansions in 2005 through 2007.

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, March 2011).

In 2012, Apex Geoscience conducted a geotechnical investigation for Landfill expansion activities planned at the western portion of the Landfill where surface lignite mining operations had previously been conducted to a depth of 50 to 100 feet using a dragline, and the spoils (reclaimed soil) were returned to the excavation. The report concluded the Landfill embankments would be stable with side slopes of 3:1 (Apex Geoscience, 2013).

In December 2015, Auckland Consulting further expanded the groundwater monitoring well system at the Plant, including installation of six monitoring wells (AD-30 through AD-35) (Auckland Consulting, 2016).

In 2016, Auckland Consulting conducted a geotechnical evaluation of the 2018 Landfill Lateral Expansion area, including installation of eight soil borings (B1 through B8) with total depths ranging from 40 to 62 feet below ground surface (bgl). Soil boring locations are shown on **Figure 11**, and copies of the soil boring logs are provided in **Appendix A.** Based on the results of the 2016 geotechnical evaluation, including slope stability modeling and settlement analysis, Auckland Consulting concluded the 2018 Landfill Lateral Expansion will be structurally stable with maximum side slopes of 3:1 to a maximum disposal height of 120 feet (Auckland, November 2016).

In 2018, Auckland Consulting installed seven piezometers (PZ-1 through PZ-7) within the 2018 Landfill Lateral Expansion area to obtain detailed depth to groundwater and groundwater flow direction data prior to construction of the Lateral Expansion. The piezometers were completed in the uppermost water-bearing unit with total depths ranging from 14 to 20 feet bgl. Piezometer locations are shown on **Figure 11**, and piezometer completion data is provided in **Appendix A.**

In November 2018, AD-35 was decommissioned due to landfill expansion activities. AD-36 was installed in April 2019 as replacement of AD-35 as a new downgradient monitoring well in the CCR well network. Eight background samples were collected from August 2019 to July 2020 to establish Appendix III background values at AD-36 to incorporate AD-36 into the CCR well network (AEP, 2021). AD-36 has been included in the subsequent semi-annual sampling events completed in November 2020, May 2021, and November 2021. The well construction log and well construction report for AD-36 are included in **Appendix B**.

2.4 Hydrogeologic Setting

2.4.1 General

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Site in the area of the Landfill Stormwater Runoff Pond. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of up to approximately 100 feet in Harrison county, Texas (Broom, 1966). As shown on Geologic Cross Sections C-C’ (**Figure 6**) and D-D’ (**Figure 7**), a thick sand stratum is located below and adjacent to the Landfill between an elevation of approximately 270 feet and 330 feet amsl. This sand stratum likely corresponds to the Carrizo Sand based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

The Carrizo Sand is underlain by the Eocene-age Wilcox Formation, which outcrops in topographically low areas near the Sabine River to the south and southeast of the Plant (Flawn, 1965). The Wilcox Formation consists of interbedded sand and clay with seams of lignite, and attains a thickness of approximately 700 feet (Broom, 1966). As shown on Geologic Cross Section D-D’ (**Figure 7**), a lignite seam was encountered below an elevation of approximately 270 feet amsl during drilling of monitoring well AD-24 at the south end of the Site. This lignite seam likely corresponds to the top of the Wilcox Formation based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

These features are further illustrated on five lines of cross section that were prepared through the existing Landfill Area, with three lines trending from west to east (A-A’; B-B’; C-C’), and the other two lines trending from north to south (D-D’; E-E’). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure 4** (A-A’) through **Figure 8** (E-E’).

2.4.2 2018 Landfill Lateral Expansion Area

Based on the hydrogeologic data obtained from soil borings, monitoring wells, and piezometers installed in the 2018 Landfill Lateral Expansion area, four lines of cross section were prepared through the 2018 Landfill Lateral Expansion area. The cross section location map is included as **Figure 11** and the lines of cross section are included as **Figure 12** (F-F’), **Figure 13** (G-G’), **Figure 14** (H-H’), and **Figure 15** (I-I’).

As shown on **Figures 12** through **15**, a reddish-brown to gray clayey and silty sand stratum is located below the Lateral Expansion area between an elevation of approximately 280 feet and 330 feet amsl. This sand stratum likely corresponds to the Carrizo Sand based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

As shown on **Figures 12** through **15**, a clay stratum with an average thickness of approximately 10 feet is located below the sand stratum, and a lignite seam is present below the clay stratum at an elevation of approximately 270 feet amsl. As discussed above in Section 2.4.1, this lignite seam likely corresponds to the top of the Wilcox Formation based on geologic maps of the Site area (Broom, 1966; Flawn, 1965).

2.4.3 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1˚ Fahrenheit (F) in January to 83.8˚F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.4 Regional and Local Geologic Setting

The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant where the existing Landfill, 2018 Landfill Lateral Expansion, and Landfill Stormwater Runoff Pond are located (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 “*Ground-Water Resources of Harrison County, Texas*” (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology “*Geologic Atlas of Texas – Tyler Sheet*” (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K “*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*” (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled “*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*” (ETTL, 2010).

2.4.5 Surface Water and Surface Water Groundwater Interactions

Figures 9 and **10** are potentiometric surface maps based on January 2016 and August 2017 water level data, respectively, for the uppermost water bearing unit at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1** and has been updated to include data through 2021. As shown on **Figures 9** and **10**, shallow groundwater flow direction in the Landfill area is southwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The Landfill is located approximately 400 feet west of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980’s. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figures 9** and **10**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore, shallow groundwater in the Landfill area does not discharge into Brandy Branch Reservoir. Brandy Branch Reservoir likely recharges the uppermost water bearing unit in the southern portion of the Site, where the pool level in the Reservoir (340 feet amsl) is higher than water level elevations in monitoring wells located southwest (downslope) of the Reservoir.

Figure 16 is a June 2018 potentiometric surface map for the uppermost water-bearing unit in the 2018 Landfill Lateral Expansion area, and water level elevations for the 2018 Landfill Lateral Expansion area piezometers are summarized on **Table 2**. As shown on **Figure 16** and potentiometric figures for the semi-annual sampling from 2019 to 2021 included in **Appendix C**, shallow groundwater flow direction in the 2018 Landfill Lateral Expansion area is westerly toward the Landfill Stormwater Runoff Pond at a hydraulic gradient of approximately 0.02 foot per foot. Water level elevations in the 2018 Landfill Lateral Expansion area piezometers were higher than the surface water elevation of the Landfill Stormwater Runoff Pond (approximately 298 feet amsl), which indicated shallow groundwater in the 2018 Landfill Lateral Expansion area discharges into the Landfill Stormwater Runoff Pond.

2.4.6 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled directly east of the Landfill in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 330 to 426 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled directly south of the Landfill by Amoco Production Company in 1991 for use as an oil field rig supply well. The water well was screened from 163 to 243 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The third closest water well was reportedly drilled approximately 200 feet southwest of the Landfill by Matador Operating in 2000 for use as an industrial well. The water well was screened from 340 to 420 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth and is located approximately ¼-mile east (upgradient) of the Pirkey Power Plant.

3 Groundwater Monitoring Well Network Evaluation

The existing monitoring well network present at the Site was evaluated to determine if any of the wells were viable for continued use as part of the groundwater monitoring well network or also retained as part of a larger groundwater hydraulic monitoring well network. The hydrogeologic conditions were also evaluated to determine if the uppermost aquifer unit has an effective well network. The evaluation was completed in accordance with 40 CFR 257.91 and 30 TAC 352.911 to have an established monitoring well network that effectively monitors the uppermost aquifer up gradient and down gradient of the Site. The up gradient wells represent background groundwater quality and the down gradient wells are to be placed down gradient of the CCR unit boundary to monitor water quality.

3.1 Hydrostratigraphic Units

3.1.1 Horizontal and Vertical Position Relative to CCR Unit

Geologic data from soil borings, piezometers, and monitoring wells installed at the Site show the uppermost aquifer in the existing Landfill Area is a very fine to fine grained clayey and silty sand stratum located below and adjacent to the existing Landfill between an elevation of approximately 270 feet and 330 feet amsl (**Appendix B**). The location of the uppermost water bearing unit relative to the existing Landfill is shown on cross section C-C' (**Figure 6)** and cross section D-D' (**Figure 7)**.

The location of the uppermost water bearing unit relative to the 2018 Landfill Lateral Expansion is shown on cross section F-F' (**Figure 12**), cross section G-G' (**Figure 13**), H-H' (**Figure 14**), and cross section I-I' (**Figure 15**). As shown on these geologic cross sections, the uppermost aquifer in the Landfill Lateral Expansion area is a clayey and silty sand stratum located between an elevation of approximately 280 feet and 330 feet amsl. Clay interbeds are present within the sand stratum, but the clay interbeds are discontinuous, indicating the entire saturated thickness of the sand stratum between approximately 280 feet and 330 feet amsl in the Lateral Expansion area is in hydraulic communication and represents the uppermost aquifer.

3.1.2 Overall Flow Conditions

Groundwater is recharged from regional precipitation infiltration. The uppermost aquifer (clayey and silty sand) is expected to have a hydraulic conductivity of approximately 10^{-4} centimeters per second (Fetter, 1980). Based on the hydraulic conductivity and saturated thickness in the Landfill area (up to 60 feet), the yield of the uppermost aquifer is anticipated to exceed the TCEQ non-useable (Class 3) limit of 150 gallons per day (TCEQ, 2010).

Groundwater elevations from the plant monitoring wells are summarized on **Table 1** and piezometer data is summarized on **Table 2**. The plant-wide comprehensive groundwater elevation data set from August 24, 2017 is depicted on **Figure 10**. Sitewide potentiometric surface maps from 2019 to 2021 are also included in **Appendix C**. The groundwater flow direction in the Landfill area is south to southwesterly towards Hatley Creek, which is located approximately one mile west of the Site.

Current groundwater elevations in the Landfill 2018 Lateral Expansion area are summarized on **Table 1-**, and a June 22, 2018 piezometric surface map is depicted on **Figure 16,** and potentiometric surface maps for sampling events completed from 2019 to 2021 are included in **Appendix C**. As shown on these figures, shallow groundwater flow direction in the 2018 Landfill Lateral Expansion area is westerly toward the Landfill Stormwater Runoff Pond at a hydraulic gradient of approximately 0.02 foot per foot. Water level elevations in the 2018 Landfill Lateral Expansion area piezometers are higher than the surface water elevation of the Landfill Stormwater Runoff Pond (approximately 298 feet amsl), which indicates shallow groundwater in the 2018 Landfill Lateral Expansion area discharges into the Landfill Stormwater Runoff Pond.

3.2 Uppermost Aquifer

3.2.1 CCR Rule Definition

The CCR rule definitions for an aquifer and the uppermost aquifer as specified in 40 CFR 257.53 and 30 TAC 352.3 indicates an aquifer is a geologic formation capable of yielding usable quantities of groundwater to wells or springs while an uppermost aquifer is defined as the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers, that are hydraulically interconnected with this aquifer within the facility's property boundary. Upper limit is measured at a point nearest to the natural groundwater surface to which the aquifer rises during the wet season.

3.2.1.1 Common Definitions

An aquifer is commonly defined as a geologic unit that stores and transmits water (readily or at sufficient flow rates) to supply wells and springs (USGS, 2015; Fetter, 2001). The uppermost aquifer is considered the first encountered aquifer nearest to the CCR unit.

3.2.2 Identified Onsite Hydrostratigraphic Unit

The identified Site hydrostratigraphic unit in the Landfill area is the clayey and silty sand stratum that is located between an elevation of approximately 270 and 330 feet amsl.

3.3 Review of Existing Monitoring Well Network

3.3.1 Overview

A well construction table that summarizes the location, ground surface elevation, borehole depth, installation date, and associated well construction details of the monitoring well network is included as **Table 3**.

Monitoring wells AD-8, AD-12, AD-16, AD-23, AD-24, AD-25, AD-26, AD-27, AD-34, and AD-35 were previously installed at the Site to monitor the uppermost aquifer (clayey and silty sand stratum) associated with the Landfill. AD-35 was decommissioned in 2018 and AD-36 was installed as a replacement in 2019. As discussed above in Section 3.1.1, the uppermost aquifer below and adjacent to the existing Landfill is up to 60 feet thick and is located between an elevation of approximately 270 and 330 feet amsl. The uppermost aquifer below the Landfill Lateral Expansion area is located between an elevation of approximately 280 and 330 feet amsl.

3.3.2 Gaps in Monitoring Network

As shown on **Figure 10** and subsequent potentiometric maps in **Appendix C** shallow groundwater flow direction in the existing Landfill area is south to southwesterly. Four existing monitoring wells (AD-8, AD-12, AD-16, and AD-27) are located up gradient north and northeast of the Landfill and will be utilized as up gradient monitoring wells for the Landfill.

As shown on **Figure 10** and subsequent potentiometric maps in **Appendix C**, three existing monitoring wells (AD-23, AD-34, and AD-36) are located downgradient (south) of the Landfill and are currently utilized to monitor groundwater quality downgradient of the Landfill CCR unit. Monitoring well MW-35 was located within the footprint of the proposed 2018 Landfill Lateral Expansion and was plugged by a Texas Department of Licensing and Regulation (TDLR) licensed water well driller. This data gap was addressed by installation of new downgradient monitoring well AD-36. As shown on potentiometric surface maps included in **Appendix C**, monitoring well AD-36 is located on the west (downgradient) side of the 2018 Landfill Lateral Expansion. With the addition of monitoring well AD-36 as a replacement for monitoring well AD-35, there are no gaps in the groundwater monitoring network for the Landfill.

4 Monitoring Well Network and PE Certification

The groundwater monitoring well network is intended to meet specifications stated in 40 CFR 257.91 and 30 TAC 352.911. These wells are further discussed below with respect to location to the Landfill (up gradient or down gradient), well depth, and well construction. The monitoring well network provides an adequate understanding of groundwater quality, hydraulics, and groundwater flow at the Landfill.

4.1 Monitoring Well Network Distribution

Four up gradient well locations (existing monitoring wells AD-8, AD-12, AD-16, and AD-27) and three downgradient well locations (existing monitoring wells AD-23, AD-34, and AD-36) are currently utilized as the groundwater quality monitoring well network for the Landfill. During the 2018 Landfill Lateral Expansion construction activities, monitoring well AD-35 was plugged and replaced with a new monitoring well (AD-36) installed directly west (downgradient) of the Lateral Expansion. In addition, existing side gradient monitoring wells AD-25 and AD-26 may be utilized as piezometers to obtain additional groundwater flow direction and gradient data for the Landfill.

4.1.1 Location

The monitoring well network for groundwater quality of the uppermost aquifer at the Landfill is summarized on **Table 4** and illustrated on **Figure 17.**

4.1.2 Depth

The screen depths for the monitoring wells recommended for inclusion in the monitoring network are within the shallow saturated sand stratum (uppermost aquifer) that occurs between an elevation of approximately 270 and 330 feet amsl in the existing Landfill area, and between an elevation of approximately 280 and 330 feet amsl in the Landfill Lateral Expansion area, as shown on Geologic Cross Sections C-C’ (**Figure 6**), D-D’ (**Figure 7**), F-F’ (**Figure 12**), G-G’ (**Figure 13**), H-H’ (**Figure 14**), and I-I’ (**Figure 15**). The screen elevations are presented in **Table 4**.

4.1.3 Well Construction

As discussed above in Section 3.3.2, the gap in the monitoring well network for the uppermost aquifer at the Landfill due to the expansion activities has been previously addressed by plugging of monitoring well AD-35 in 2018 and installation of new monitoring well AD-36 in 2019. Well construction data for the monitoring well network are summarized on **Tables 3** and **4**, and the monitoring well completion diagrams for the existing monitoring wells are provided in **Appendix B**.

4.2 Professional Engineer's Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, the proposed groundwater monitoring system for the Landfill CCR unit is adequate to meet the requirements of 40 CFR Part 257.91 and 30 TAC 352.911.

NOTES:

(a) Source: Apex Geoscience Inc. (March 23, 2011) and Akron Consulting, LLC (2019).

(b) Screen length and screened intervals for AD-2 through AD-12 estimated from video surveillance (Apex Geoscience Inc., March 23, 2011).

(c) Souce: EETL (October 2010).

(d) Source: Auckland Consulting LLC (January 26, 2016). Monitoring wells AD-30 through AD-35 installed during December 2015. AD-36 installed April 2019.

(e) AD-24 was abandoned on January 26, 2016

(f) AD-34 water level observations are often flowing artesian (water upwelling out of the well casing with an entered 0.00 depth to water) and the actual water level is greater.

(g) AD-35 was abandoned on November 13, 2018

Groundwater Elevation Source: AEP, Pirkey Monitoring Well Groundwater Elevations through November 2021.

--- = Not Measured

ft = Feet

bls = Below land surface

msl = mean sea level

Elev. = Elevation in feet above mean sea level

NOTES:

Elevations in feet above mean sea level.

(a) Source: Apex Geoscience Inc. (March 23, 2011) and Akron Consulting, LLC (2019).

(b) Screen length and screened intervals for AD-2 through AD-12 estimated from video surveillance (Apex Geoscience Inc., March 23, 2011). Top of sand pack estimated 2 feet above top of screened interval.

(c) Souce: EETL (October 2010).

(d) Source: Aukland Consulting LLC (January 26, 2016 and April 2019).

(e) AD-24 was abandoned on January 26, 2016

(f) AD-35 was abandoned on November 13, 2018

NA = Data not available

ft = feet

bls = below land surface

msl = mean sea level

Table 4
Monitoring Well Network
AEP Pirkey Power Plant-Landfill CCR
Hallsville, Harrison County, Texas

Well ID	Hydrostratigraphic Unit Target	Location Description		Screen Top Elevation (ft amsl)	Screen Bottom Elevation (ft amsl)	Screen Length (ft)	Comments
<u>Upgradient</u>							
AD-8	Uppermost Water-Bearing Unit	Northeast of Landfill	Upgradient	336.9	321.9	15	Existing well installed in 1983; well will be utilitzed to establish backgroud water quality
AD-12	Uppermost Water-Bearing Unit	Northeast of Stack Out Area	Upgradient	347.8	327.8	20	Existing well installed in 1986; well will be utilitzed to establish backgroud water quality
AD-16	Uppermost Water-Bearing Unit	North of Landfill	Upgradient	341.8	321.8	20	Existing well installed in 2010; well will be utilitzed to establish backgroud water quality
AD-27	Uppermost Water-Bearing Unit	Northwest of Landfill	Upgradient	332.3	312.3	20	Existing well installed in 2010; well will be utilitzed to establish backgroud water quality
<u>Downgradient</u>							
AD-23	Uppermost Water-Bearing Unit	South of Landfill	Down gradient	331.7	311.7	20	Existing well installed in 2010; uppermost shallow aquifer adjacent to Landfill - downgradient
AD-34	Uppermost Water-Bearing Unit	Southwest of Landfill	Down gradient	294.6	279.6	15	Existing monitoring well installed during December 2015 in uppermost shallow aquifer adjacent to Landfill - downgradient.
AD-35[(a)]	Uppermost Water-Bearing Unit	South of Landfill	Down gradient	313.0	298.0	15	Monitoring well installed during December 2015 in uppermost shallow aquifer adjacent to Landfill - downgradient. Was plugged during 2018 Landfill Cell construction on November 13, 2018 and replaced with AD-36.
AD-36	Uppermost Water-Bearing Unit	South of Landfill, West of 2018 Landfill Cell	Down gradient	301.5	291.5	10.0	New well installed on April 24, 2019 in uppermost shallow aquifer adjacent to Landfill - downgradient.
<u>Piezometers</u>							
AD-25	Uppermost Water-Bearing Unit	West of Landfill	Side gradient	324.2	304.2	20	Existing well installed in 2010; uppermost shallow aquifer adjacent to Landfill - side gradient
AD-26	Uppermost Water-Bearing Unit	West of Landfill	Side gradient	332.4	302.4	30	Existing well installed in 2010; uppermost shallow aquifer adjacent to Landfill - side gradient

NOTES:

(a) AD-35 was abandoned on November 13, 2018.

U = Upgradient

D = Downgradient

ft = feet

amsl = above mean sea level

TDS	total dissolved solids

1. Objective

This report was prepared by ARCADIS U.S., Inc. (ARCADIS) for American Electric Power Service Corporation (AEP) to assess the adequacy of the groundwater monitoring well network included in the Coal Combustion Residual (CCR) requirements, as specified in Code of Federal Regulations (CFR) 40 CFR 257.91, for the Stack Out Area CCR Unit at the AEP H.W. Pirkey Generating Plant (Plant) located at 2400 FM 3251 in Hallsville, Harrison County, Texas (**Figure 1**). The CCR requirements include an evaluation of the adequacy of the groundwater monitoring well network to characterize groundwater quality up and down gradient of the CCR unit and an evaluation of whether the CCR unit meets up to 5 location restrictions, which include: the base of the CCR unit is 5 feet (ft) above and isolated from the uppermost aquifer, the CCR unit may not be located in a wetland, within 200 ft of the damage zone of a fault that has displacement during the Holocene, within a seismic impact zone, or in an unstable area.

Four regulated CCR units associated with the Plant were identified for review, which include the West BAP, East BAP, Stack Out Area, and Landfill (**Figure 2**). This report summarizes the evaluation of the groundwater monitoring well network in the uppermost aquifer at the Stack Out Area. The evaluation of the location restriction criteria is not included in this report and will be completed under separate cover.

This evaluation included a review of AEP-provided data associated with previously completed subsurface investigation activities in the vicinity of the Stack Out Area CCR unit, as well as publically-available geologic and hydrogeologic data. The following report also presents the current Conceptual Site Model based on all documents reviewed and will further describe the uppermost aquifer, include an evaluation of the adequacy of the existing monitoring well network, and provide recommendations for monitoring well augmentation, as necessary.

2. Background Information

The following section provides background information for the AEP H.W. Pirkey Generating Plant Stack Out Area.

2.1 Facility Location Description

The AEP H.W. Pirkey Plant is located in southern Harrison County, approximately 5 miles southeast of Hallsville, Texas, and approximately 8 miles southwest of Marshall, Texas. The Stack Out Area CCR unit is located in the central portion of the Plant, and approximately 1,200 feet northwest of Brandy Branch Reservoir (**Figures 1** and **2**).

2.2 Description of Stack Out Area CCR Unit

The following section will discuss the embankment configuration, area, volume, construction and operational history, and surface water control associated with the Stack Out Area.

2.2.1 Stack Out Area Configuration

The Stack Out Area is an approximate 7-acre storage area for stabilized flue gas desulfurization (FGD) sludge. As shown on **Figure 3**, the Stack Out Area is located directly south of the Surge Pond, directly west of Thickener Tanks 1A and 1B, and directly east of a road that runs south to the on-site Landfill. The dimensions of the Stack Out Area are approximately 650 feet from north to south by 450 feet from east to west.

Stabilized FGD sludge is temporarily stockpiled directly above natural ground surface (native clay) in the Stack Out Area using a radial stacker. The maximum height of the stabilized FGD sludge piles are approximately 41 feet above ground surface. There are no solids retention structures in the Stack Out Area. The stabilized FGD sludge piles are located no closer than approximately 50 feet from the perimeter of the Stack Out Area, thereby preventing the stabilized FGD sludge from migrating beyond the boundaries of the Stack Out Area.

2.2.2 Area/Volume

The Stack Out Area is approximately 7 acres in size. However, as discussed above in Section 2.2.1, the CCR piles in the Stack Out Area are located no closer than approximately 50 feet from the perimeter of the Stack Out Area, therefore the effective storage area of the Stack Out Area is approximately 4.4 acres (550 feet by 350 feet), and the maximum CCR storage volume based on a maximum CCR pile height of 41 feet is 180 acre feet.

2.2.3 Construction and Operational History

The H.W. Pirkey Power Plant was constructed in 1983 and 1984, and began operation in 1985. Throughout the life of the Plant, CCR materials (fly ash, bottom ash, economizer ash, FGD sludge) have been generated. The Stack Out Area receives stabilized FGD sludge (**Figure 3**). Prior to storing the FGD sludge in the Stack Out Area, the FGD sludge is dewatered using belt presses, and the dewatering fluid is routed to the Surge Pond for reuse as FGD makeup water. The stabilized FGD sludge is then stockpiled in the Stack Out Area using a radial stacker with an approximate 3-foot-wide by 120-foot-long conveyor belt.

The stabilized FGD sludge is temporarily stored at the Stack Out Area. The stabilized FGD sludge is removed using front-end loaders or similar equipment, placed into trucks, and disposed of at the on-site Landfill CCR Unit located near the south end of the Plant.

Lithologic data from soil borings and monitoring wells confirm the native soils underling the Stack Out Area consist of low-permeability clay. As shown on Geologic Cross Sections B-B' (**Figure 5**) and E-E' (**Figure 8**), the native clay directly below the Stack Out Area extends from the surface to an average depth of approximately 20 feet. Therefore, as shown on **Figures 5** and **8**, the separation distance between the base of the Stack Out Area and uppermost aquifer exceeds 5 feet.

2.2.4 Surface Water Control

The Stack Out Area contains dewatered FGD sludge that is stockpiled using a radial stacker, therefore no sluice water is present in the Stack Out Area. Storm water in the Stack Out Area follows surface topography via gravity sheet flow. The ground surface elevation in the Stack Out Area ranges from approximately 360 to 365 feet amsl (Akron Consulting, 2015). Storm water flow in the Stack Out Area is in a general northerly direction to the Surge Pond, which is a below-grade (incised) non-CCR unit.

2.3 Previous Investigations

The initial soils investigation and design of the Plant was provided in a January 31, 1983 report prepared by Sargent & Lundy entitled "*Henry W. Pirkey Power Plant, Design Summary for Lignite Storage Area and Wastewater Pond Facilities*". This investigation included advancement of soil borings throughout the Plant, including the Stack Out Area.

In 2009, ETTL Engineers & Consultants (ETTL) conducted geotechnical investigations of earthen embankments associated with several ponds at the Plant. The Stack Out Area was not included in this evaluation because there are no earthen embankments in the Stack Out Area (ETTL, 2010).

In 2010 and January 2011, Apex Geoscience expanded the groundwater monitoring well system at the Plant, including installation of monitoring wells AD-16 through AD-29. Apex Geoscience also conducted video surveillance of the existing monitoring wells and plugged monitoring wells MW-1, MW-5, MW-6, MW-9, MW-11, MW-14, MW-15, M-2, and M-3 (Apex Geoscience, 2011).

In 2011, Johnson & Pace performed hydraulic analysis of several ponds at the Plant. The Stack Out Area was not included in this evaluation because there is no impounded water in the Stack Out Area (Johnson & Pace, May 2011).

In December 2015, Auckland Consulting further expanded the groundwater monitoring well system at the Plant, including installation of six monitoring wells (AD-30 through AD-35) (Auckland Consulting, 2016).

2.4 Hydrogeologic Setting

The site area is located within the West Gulf Coastal Plain. Cretaceous formations crop out in belts that extend in a northeasterly direction parallel to the Gulf of Mexico, and dip gently southeast. The central and northern portions of the Plant are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation consists predominantly of clay and fine grained sand, and attains a maximum thickness of approximately 100 feet (Broom, 1966).

The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern portion of the Plant. The Carrizo Sand consists of fine to medium grained sand interbedded with silt and clay, and attains a thickness of approximately 100 feet (Broom, 1966).

These features are further illustrated on five lines of cross section that were prepared through the Stack Out Area, with three lines trending from west to east (A-A'; B-B'; C-C'), and the other two lines trending from north to south (D-D'; E-E'). The cross section location map is included as **Figure 3** and the lines of cross section are included as **Figure 4** (A-A') through **Figure 8** (E-E').

2.4.1 Climate and Water Budget

Average temperatures in Harrison County, Texas range from 47.1° Fahrenheit (F) in January to 83.8°F in July, and the mean annual growing season is 238 days. Average annual precipitation (including liquid water equivalent from snowfall) is approximately 47 inches (Broom, 1966).

2.4.2 Regional and Local Geologic Setting

The central and northern portions of the Plant, including the Stack Out Area, are located on the outcrop of the Eocene-age Recklaw Formation. The Recklaw Formation is underlain by the Eocene-age Carrizo Sand, which outcrops in the topographically low southern end of the Plant (Broom, 1966; Flawn, 1965).

Detailed regional geologic characterization can be found in several published reports including Texas Water Development Report 27 "*Ground-Water Resources of Harrison County, Texas*" (Broom, 1966), The University of Texas at Austin Bureau of Economic Geology "*Geologic Atlas of Texas – Tyler Sheet*" (Flawn, 1965), and U.S. Geological Survey Open-File Report 88-450K "*Petroleum Geology and the Distribution of Conventional Crude Oil, Natural Gas, and Natural Gas Liquids, East Texas Basin*" (USGS, 1988).

Detailed regional and site geologic characterization can also be found in the 2010 ETTL report entitled "*Geotechnical Investigation, Pirkey Power Station, Existing Ash, Surge, Lignite and Limestone Runoff, and Landfill Stormwater Ponds Embankment Investigation, Hallsville, Texas*" (ETTL, 2010).

2.4.3 Surface Water and Surface Water Groundwater Interactions

Figure 9 is a potentiometric surface map based on January 2016 water level data for the uppermost aquifer at the Site, and water level elevations in the Site monitoring wells are summarized on **Table 1**. As shown on **Figure 9**, shallow groundwater flow direction in the Stack Out Area is northwesterly at an average hydraulic gradient of approximately 0.01 foot per foot.

The Stack Out Area is located approximately 1,200 feet northwest of Brandy Branch Reservoir, which was dammed during Plant construction in the 1980's. The normal pool level of Brandy Branch Reservoir is approximately 340 feet amsl. As shown on **Figure 9**, shallow groundwater flow direction at the Site generally follows surface topography to the west and southwest toward Hatley Creek, which is located in a topographically low area approximately one mile west of the Site. Therefore shallow groundwater in the Stack Out Area does not discharge into Brandy Branch Reservoir.

2.4.4 Water Users

A water well inventory conducted by Banks Information Solutions showed 12 water wells had been drilled within a ½-mile radius of the Site (Banks, 2015). The nearest water well was reportedly drilled approximately 1,000 feet north of the Stack Out Area in 2004 by Bennett Drilling for use as a rig supply well. The water well was screened from 350 to 430 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

The second closest water well was reportedly drilled approximately ¼-mile west (downgradient) of the Stack Out Area for NFR Energy in 2008 for use as a rig supply well. The water well was screened from 250 to 310 feet below ground surface, therefore this water well is completed in a deeper water bearing unit relative to the uppermost water-bearing unit at the Site.

All of the water wells identified within a ½-mile radius of the Site were drilled to total depths of 160 feet or deeper except one water well (Well ID: 35-37-4E) that was drilled to a total depth of 55 feet in 1982. This water well was completed with concrete tile from the surface to total depth, and is located approximately ¼-mile east (upgradient) of the Pirkey Power Plant.

3. Groundwater Monitoring Well Network Evaluation

The existing monitoring well network present at the Site was evaluated to determine if any of the wells were viable for continued use as part of the groundwater monitoring well network or also retained as part of a larger groundwater hydraulic monitoring well network. The hydrogeologic conditions were also evaluated to determine if the uppermost aquifer unit has an effective well network. The evaluation was completed in accordance with 40 CFR 257.91 to have an established monitoring well network that effectively monitors the uppermost aquifer up gradient and down gradient of the Site. The up gradient wells represent background groundwater quality and the down gradient wells are to be placed down gradient of the CCR unit boundary to monitor water quality.

3.1 Hydrostratigraphic Units

3.1.1 Horizontal and Vertical Position Relative to CCR Unit

Geologic data from soil borings, piezometers, and monitoring wells installed at the Site show the uppermost aquifer in the Stack Out Area is a very fine to fine grained clayey and silty sand stratum with an average thickness of approximately 20 feet that is located between an elevation of approximately 320 and 340 feet amsl (**Appendix A**). The base of the Stack Out Area is at an elevation of 360 feet amsl. The separation distance between the uppermost aquifer and the base of the Stack Out Area ranges from approximately 10 to 20 feet. This separation distance is further illustrated on cross section B-B' (**Figure 5)** and cross section E-E' (**Figure 8)**.

3.1.2 Overall Flow Conditions

Groundwater is recharged from regional precipitation infiltration. The uppermost aquifer unit (clayey and silty sand) is expected to have a hydraulic conductivity of approximately 10^{-4} centimeters per second (Fetter, 1980). Based on the hydraulic conductivity and saturated thickness in the Stack Out Area (approximately 20 feet), the yield of the uppermost aquifer is anticipated to exceed the TCEQ non-useable (Class 3) limit of 150 gallons per day (TCEQ, 2010).

Available groundwater elevations are summarized on **Table 1** for 2011 through 2016. The most recent comprehensive groundwater data set from January 20, 2016 is depicted on **Figure 9**. The groundwater flow direction in the Stack Out Area is northwesterly towards Hatley Creek, which is located approximately one mile west of the Site.

3.2 Uppermost Aquifer

3.2.1 CCR Rule Definition

Per 40 CFR 257.60(a), new CCR landfills, existing and new CCR surface impoundments, and all lateral expansions of CCR units must be constructed with a base that is located no less than 1.52 meters (five ft) above the upper limit of the uppermost aquifer, or must demonstrate there will not be an intermittent, recurring, or sustained hydraulic connection between any portion of the base of the CCR unit and the uppermost aquifer due to normal fluctuations in groundwater elevations (including the seasonal high conditions).

The CCR rule definitions for an aquifer and the uppermost aquifer as specified in 40 CFR 257.53 indicates an aquifer is a geologic formation capable of yielding usable quantities of groundwater to wells or springs while an uppermost aquifer is defined as the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers, that are hydraulically interconnected with this aquifer within the facility's property boundary. Upper limit is measured at a point nearest to the natural groundwater surface to which the aquifer rises during the wet season.

3.2.1.1 Common Definitions

An aquifer is commonly defined as a geologic unit that stores and transmits water (readily or at sufficient flow rates) to supply wells and springs (USGS, 2015; Fetter, 2001). The uppermost aquifer is considered the first encountered aquifer nearest to the CCR unit.

3.2.2 Identified Onsite Hydrostratigraphic Unit

The identified Site hydrostratigraphic unit in the Stack Out Area is the clayey and silty sand stratum that is located between an elevation of approximately 320 and 340 feet amsl.

3.3 Review of Existing Monitoring Well Network

3.3.1 Overview

The Site was visited by ARCADIS and AEP personnel on August 19, 2015 to review existing well network conditions and locations. A well construction table that summarizes the location, ground surface elevation, borehole depth, installation date, and associated well construction details of the monitoring well network is included as

Table 2. Photo documentation of the located wells during the August 19, 2015 site visit is provided in **Appendix B**.

Monitoring wells AD-7, AD-12, AD-13, and AD-22 were previously installed at the Site to monitor the uppermost water-bearing unit (clayey and silty sand stratum) associated with the Stack Out Area. As discussed above in Section 3.1.1, the uppermost water-bearing unit below the Stack Out Area is approximately 20 feet thick and is located between an elevation of approximately 320 and 340 feet amsl.

3.3.2 Gaps in Monitoring Network

As shown on Geologic Cross Sections B-B' (**Figure 5**) and E-E' (**Figure 8**), existing monitoring wells AD-7 and AD-22 are screened in the uppermost water-bearing unit downgradient (northwest) of the Stack Out Area, and will be utilized as downgradient monitoring wells for the Stack Out Area. Existing monitoring wells AD-12 and AD-13 are screened in the uppermost water-bearing unit up gradient (east) of the Stack Out Area, and will be utilized as up gradient monitoring wells for the Stack Out Area.

As shown on **Figure 9**, shallow groundwater flow direction in the Stack Out Area is northwesterly. Two existing monitoring wells (AD-7 and AD-22) were located hydraulically downgradient of the Stack Out Area during the August 19, 2015 site visit, and three downgradient monitoring wells are required to monitor groundwater quality downgradient of a CCR unit. This data gap was addressed by installation of new downgradient monitoring well AD-33 during December 2015 as shown on **Figure 9** and **Figure 10**. With the addition of monitoring well AD-33 on the west side of the Stack Out Area, there are no gaps remaining in the groundwater monitoring network for the Stack Out Area.

4. Recommended Monitoring Network and PE Certification

The recommended existing groundwater monitoring well network is intended to meet specifications stated in 40 CFR 257.91. Recommended wells are further discussed with respect to location to the Stack Out Area (up gradient or down gradient), well depth, and well construction. The recommended network would provide an improved understanding of groundwater quality, hydraulics, and groundwater flow at the Stack Out Area.

4.1 Recommended Monitoring Well Network Distribution

Two up gradient well locations (existing monitoring wells AD-12 and AD-13) and three down gradient well locations (existing monitoring wells AD-7, AD-22, and AD-33) are recommended to establish a groundwater quality monitoring well network for the Stack Out Area.

4.1.1 Location

The recommended monitoring well network for groundwater quality of the uppermost aquifer at the Stack Out Area is summarized on **Table 3** and illustrated on **Figure 10.**

4.1.2 Depth

The screen depths for the monitoring wells recommended for inclusion in the monitoring network are within the shallow saturated sand stratum (uppermost aquifer) that occurs between an elevation of approximately 320 and 340 feet amsl as shown on Geologic Cross Sections B-B' (**Figure 5**) and E-E' (**Figure 8**). The screen elevations are presented in **Table 3**.

4.1.3 Well Construction

As discussed above in Section 3.3.2, the gap in the monitoring well network for the uppermost aquifer at the Stack Out Area was addressed by installation of monitoring well AD-33 during December 2015. Monitoring well AD-33 was installed by a Texas Department of Licensing and Regulation (TDLR)-licensed water well driller. Well construction data for the monitoring well network are summarized on **Tables 2** and **3**, and the monitoring well completion diagrams are provided in **Appendix A.**

4.2 Professional Engineer's Certification

I, Kenneth J. Brandner, certify that this report was prepared under my direction and supervision, and that the information contained herein is true and accurate to the best of my knowledge. Based on my experience and knowledge of the site, the proposed groundwater monitoring system will be adequate to meet the requirements of 40 CFR Part 257.91.

Acronyms and Abbreviations:
NA = Data not available
ft = feet
bls = below land surface
msl = mean sea level

Table 3
Proposed Well Network
AEP Pirkey Power Plant - Stack Out Area
Hallsville, Harrison County, Texas

Well ID	Exisiting/ Proposed	Hydrostratigraphic Unit Target	Location Description		Screen Top Target Elevation[a] (ft amsl)	Screen Bottom Target Elevation[a] (ft amsl)	Screen Length (ft)	Comments
Upgradient								
AD-12	Exisiting	Uppermost Water-Bearing Unit	Northeast of Stack Out Area	Upgradient	347.8	327.8	20	Existing well installed in 1986; well will be utilitzed to establish backgroud water quality
AD-13	Exisiting	Uppermost Water-Bearing Unit	East of Stack Out Area	Upgradient	331.5	321.5	10	Existing well installed in 1988; well will be utilitzed to establish backgroud water quality
Downgradient								
AD-7	Existing	Uppermost Water-Bearing Unit	Northwest of Stack Out Area	Down gradient	339.6	319.6	20	Existing well installed in 1983; uppermost shallow aquifer adjacent to Stack Out Area - downgradient
AD-22	Existing	Uppermost Water-Bearing Unit	West of Stack Out Area	Down gradient	345.6	325.6	20	Existing well installed in 2010; uppermost shallow aquifer adjacent to Stack Out Area - downgradient
AD-33	Existing	Uppermost Water-Bearing Unit	West of Stack Out Area	Down gradient	344.3	329.3	15	New monitoring well installed during December 2015 in uppermost shallow aquifer adjacent to Stack Out Area - downgradient

Footnotes:

a. Target elevations are an estimated range.

Acronyms and Abbreviations:

U=Upgradient
D=Downgradient
ft = feet
amsl = above mean sea level

POWER℠

BOUNDLESS ENERGY™

Table of Contents

1. Introduction

The following sections address the Texas Commission on Environmental Quality (TCEQ) Coal Combustion Residual (CCR) rule (30 TAC 352) and includes protocols and considerations for gathering groundwater samples, preserving them, proper documentation and shipping them to the analytical lab.

The TCEQ's CCR Rule requires that a monitoring program include consistent sampling and analysis procedures that are designed to ensure monitoring results that provide an accurate representation of groundwater quality at the background and down gradient wells and that a sampling and analysis program be developed that includes procedures and techniques for:

- Sample collection
- Sample preservation and shipment
- Analytical procedures
- Chain of custody control
- Quality assurance and quality control
- Statistical analysis procedures

The purpose of this groundwater sampling and analysis plan (GW-SAP) is to lay out these details and is aimed at satisfying the monitoring of the PE-certified groundwater monitoring network according to the requirements of TCEQ's CCR Rule.

2. Sampling and Analysis Plan

This GW-SAP includes consistent sampling and analysis procedures that are protective of human health, safety, and the environment, and that are designed to ensure monitoring results that provide an accurate representation of groundwater quality.

The TCEQ's CCR Rule has a performance standard that calls for establishment of consistent sampling, laboratory analysis, and quality assurance/quality control procedures. The development of a GW-SAP in advance of performing the sampling provides an added benefit that analytical results will be less subject to variability over time. This is important because a change in sampling methods, laboratory analytical methods, or even analytical laboratories, can cause shifts in data that can complicate statistical analyses and potentially trigger a false SSI or SSL.

The TCEQ's CCR Rule requires analysis of total recoverable metals (i.e., no field filtering) in measuring groundwater quality. As a result, groundwater samples from some monitoring wells may exhibit variable levels of turbidity that can potentially trigger false SSIs or SSLs. Therefore, this sampling and analysis plan calls for the use of low-flow sampling techniques, which are designed to minimize turbidity at the time of sample collection. However, other sampling techniques may be used if low-flow sampling cannot be supported by the aquifer. This GW-SAP also includes a specification to collect an optional, filtered sample whenever turbidity is higher than a threshold of 10 NTU. If the optional field filtered samples are to be collected for a sampling event then there will be a specific instruction to collect the field filtered samples. If no specific instruction is given then field filtered samples will not be collected.

The TCEQ's CCR Rule calls for analysis of total recoverable metals, and has a performance standard that analytical methods be appropriate and accurate for groundwater analysis. There are a variety of laboratory analytical methods that meet these criteria, and selection of appropriate methods can be based on desired reporting limits, accuracy, precision, potential for interferences, and cost. A list of appropriate analytical methods is included in **Appendix C**.

Appendix B contains Instruction to sampler for sampling event. This form should be customized for a specific sampling event. This document will communicate to the sampler the scheduled date for sampling; the wells to be sampled; which parameters to the sampled; whether state parameters should be sampled. Other information pertinent to the specific sampling event may be included on this instruction sheet.

2.1 Measurement of Groundwater Level

As reference, a site map showing locations and ID of the monitoring wells is included in **Appendix A**. **Appendix B** contains monitoring well construction information and sample groundwater sampling data form. Prior to well purging and sampling, static water level in each well and piezometer are to be measured and recorded to the nearest hundredth of a foot. Static water levels for all wells and piezometers are to be taken within a 24-hour period. To measure the static water level, an electronic probe on a measuring tape is lowered into the groundwater well riser pipe. When the probe contacts the water a visual and audible alarm are activated. The static water level is established by reading the measurement on the tape to a hundredth of a foot (0.01-foot) at the top of the riser pipe, i.e., top of casing (TOC). Results are immediately recorded on the groundwater sampling data form along with the date, time, monitoring well number, and the name of the person recording the data. The probe is rinsed with deionized water before using in the first well and then after each use.

2.2 Collection and Handling of Groundwater Samples

Low flow sampling is the preferred method for collecting the groundwater samples. Therefore, the sample collector needs to be well versed in the intricacies of low flow sampling.

Low flow purging and sampling

Equipment needed

Low flow pump. The pump will have the ability to regulate flow in the range of 0.1 liters per minute to 0.5 liters per minute or a greater range.

Field parameter measurement instruments. The instruments should include instruments for measuring:

depth to water

pH

specific conductivity

turbidity

temperature

dissolved oxygen (if requested by AEP)

oxidation reduction potential (if requested by AEP)

Groundwater sampling data forms

See **Appendix B** for a check list of equipment to be considered for use.

Procedures to follow at the beginning of the sampling event.

Before beginning sampling all field instruments should be calibrated. Additional calibrations may be needed during the sampling procedure.

The instruments used to make the measurements will be instruments designed by the manufacturer to perform such measurements. The instruments will be calibrated in accordance with the manufacturer's instructions and decontaminated between each well by rinsing with deionized water or as recommended by the manufacturer. A record of the calibration procedures used and information on the specific standards used should be recorded on the Calibration Record Form (see **Appendix B** for example) or a similar form. At a minimum, a notation will be made stating that each instrument is in calibration or not in calibration.

Duplicate samples will be needed. Select suitable sampling locations for duplicates.

Blanks will be needed. Select suitable times and locations to collect blanks.

Purging and sampling procedures for each sampling location.

Decontaminate equipment

Reusable sampling equipment, including pumps, tubing, and instrumentation is decontaminated using deionized water, soap solution, or other appropriate methods after each use. The disposable equipment should be purchased in a clean state and maintained clean until used for sampling.

Measure groundwater level

If not previously measured as state in paragraph 2.1, prior to well purging or sampling, the depth to water in each well is measured and recorded. The depth to water is measured to the nearest 0.01 foot increment with a calibrated water level indicator. The probe is lowered into each well until the audible indicator sounds indicating that contact of the probe with the water surface has occurred. The depth of water is measured from the top of the casing. The top of casing has already been surveyed and its elevation is known. The data are recorded on the field log or similar form with date, time, monitoring well number, depth to water, and the name of the person recording the data. The probe is rinsed with deionized water before and after each use.

Install pump

Install the intake for the pump near the mid-point of the screened interval of the monitoring well. Minimize disturbances in the groundwater. Agitation of the groundwater will result in suspension of any particulates in the well and may result in chemistry changes in the groundwater due to aeration of the groundwater. Such conditions are to be avoided.

Measure groundwater level

The amount of groundwater drawdown needs to be checked. Ideally, only a small amount (less than one foot) of drawdown should occur as the result of purging the well. This measurement may be taken with a groundwater tape or an electronic pressure transducer or other suitable measuring instrument. This measurement may not have the same reference elevation as the depth to groundwater measurement and the measurement may not be the same value as the original depth to groundwater measurement.

Record the measurement.

Purge monitoring well

Set flow rate of pump

Start the pump at low speed and slowly increase the speed until discharge occurs. Check water level. The water level should not be lowered so that the water level is brought down to within the screened interval. That is, the pump should be operated so that the water elevation is above the screened interval. However, the groundwater level may be within the screened interval before pumping begins. In that case the water level during pumping may be within the screened interval. Check equipment for water leaks and if present fix or replace the affected equipment. Try to match pumping rate used during previous sampling event(s). Otherwise, adjust pump speed until there is little or no water level drawdown. If the minimal drawdown that can be achieved exceeds 1 foot, but remains stable, continue purging.

Monitor and record the water level and pumping rate on the groundwater sampling data form every five minutes (or as appropriate) during purging. Record any pumping rate adjustments (both time and flow rate). Pumping rates should, as needed, be reduced to the minimum capabilities of the pump to ensure stabilization of the water level. Adjustments are best made in the first fifteen minutes of pumping in order to help minimize purging time.

If the water level continues to drop at the lowest practical pumping rate then an alternate purging and sampling procedure will apply. The well will be purged of water and allowed to recharge. Sampling will occur when enough water is in the well to obtain groundwater samples. Pumping rates for sampling will be low in order to minimize entrainment of solid particles.

Monitor parameters

In order to determine if the pumped groundwater has chemically stabilized to the point where a representative sample may be taken, certain field parameters are monitored.

Field parameters will include at least pH, specific conductivity, and turbidity. Other parameters that may be included are dissolved oxygen, oxidation reduction potential, and temperature.

Field parameters stabilize

Field parameter stabilization is considered to be achieved when two consecutive readings are within the following limits:

pH (± 0.1 unit),

Specific Conductance (3%),

Turbidity (10% for values greater than 5 NTU; if three Turbidity values are less than 5 NTU, consider the values as stabilized),

Dissolved Oxygen (10% for values greater than 0.5 mg/L, if three Dissolved Oxygen values are less than 0.5 mg/L, consider the values as stabilized),

Oxidation/Reduction Potential (± 10 millivolts),

Temperature (± 3%).

Collect samples

Adequate sample volume is collected to meet the analysis requirements. Care is taken to collect an undisturbed sample to the extent practicable. The low flow pumping rate used during purging is also used for sample collection. Appropriate sample preservatives will be used for each sample collected. The preservatives may be put into the sample bottle before or immediately after the sample is collected. See Appendix C for types of sample containers needed and preservative needed.

Complete paperwork for this sample location

The groundwater sampling data form, sample labels, and chain of custody are to be complete for this sample location.

Decontaminate equipment, dispose of consumables

Any equipment that will be used on another sample location will have to be decontaminated before reuse. Any used consumable supplies needs to be collected for disposal or other disposition.

Clean up sample location and move to next sample location

The sample site should be cleaned up. Close and lock the monitoring well.

Equipment Decontamination Procedures

Reusable sampling equipment, including pumps, tubing, and instrumentation is decontaminated using deionized water, soap solution, or other appropriate methods after each use. This includes all non-dedicated equipment that is submerged in a monitoring well or otherwise contacts a groundwater sample.

Analytical Parameters

Parameters to be analyzed for the eight sample sets establishing background concentrations are shown in the table below. Both the Appendix III and Appendix IV list of parameters are used for the establishment of background concentrations. After collection of that initial set of data from eight discrete samples, the Appendix III detection monitoring parameters will continue on a semi-annual basis.

Field Filtered Samples

If directed by AEP the sampler will collect a field filtered metals sample. Field filtered metals samples will only be collected if the unfiltered groundwater has a turbidity of greater than 10 NTU. If the turbidity of the groundwater is less than 10 NTU then a sample will not be taken for the particular sampling location.

Field filtered samples are collected by placing a 0.45 micron filter on the end of the groundwater discharge tube. If single use (disposable) 0.45 micron filters are used then a new filter will be used for each sample. The filtered groundwater flowing out of the filter will be collected in a separate sample bottle and marked as a field filtered metals sample. See Appendix C for the type of sample bottle and the preservation method.

Appendix III parameters **Parameters for detection monitoring**	**Appendix IV parameters** **Parameters for assessment monitoring**
Boron (B)	Antimony (Sb)
Calcium (Ca)	Arsenic (As)
Chloride (Cl-)	Barium (Ba)
Fluoride (F-)	Beryllium (Be)
pH	Cadmium (Cd)
Sulfate (SO4-)	Chromium(Cr)
Total Dissolved Solids	Cobalt(Co)
	Fluoride (F-)
	Lead (Pb)
	Lithium(Li)
	Mercury (Hg)
	Molybdenum (Mo)
	Selenium (Se)
	Thallium (Tl)
	Radium 226 and 228 combined (Ra)

Sample Preservation and Handling

The proper containers for the parameters to be analyzed will be pre-cleaned and supplied by the contractor performing the sampling effort. Care will be taken during sampling not to overfill the sample bottles that contain preservatives. In addition to the sample bottles, one or more sample containers may be used in lieu of an in-line monitor for the field determination of parameters. The containers must be rinsed with distilled water and dried after each use or new clean sample containers utilized.

Upon completion of sampling of each monitoring well, all relevant sampling information should be recorded on the appropriate groundwater sampling data form, and the sample bottles placed in a cooler or ice chest at 40F (4C), as necessary, for storage until analyzed. If ice is the coolant then the sample bottles must be enclosed in sealed plastic bags. Once the final sample is collected at the site, the chain of custody form mentioned below must be completed. These procedures are necessary to insure that the maximum allowable holding time or maximum allowable shipping temperature for any of the parameters is not exceeded.

Sample Identification

Samples must be properly labeled. Information that should be transmitted to the laboratory includes:

- Plant name
- Sample/well identification number
- Analyses to be performed
- Date and time of collection
- Initials of field sampling personnel

A self-sticking, adhesive backed identification label will be attached to each sample container. The identification labels will be completed and attached to the appropriate container. The date and time of sampling will then be added at the time of collection.

Chain of Custody

To establish the documentation necessary to trace sample possession from the time of collection through analyses and final disposition, a chain of custody form will be filled out and must accompany each sample shipment. This record is required for legal verification of sample integrity. It also provides useful control over the routing of samples.

When transferring possession of the samples each individual relinquishing and receiving possession will sign, date and note the time on the form. Relevant information regarding the samples should be entered on the form.

The original chain of custody record must accompany the sample shipment. A chain of custody form, properly filled out, will accompany each shipment. Upon arrival at the Lab the chain of custody will serve to identify the shipment of samples.

An example of a chain of custody that fits the need and that has been used in the past at AEP is appended as **Appendix B**, as well as a sample container list to be used and preservation methods/protocols.

2.3 Laboratory Analyses

The analytical methods used by the laboratory must be appropriate for groundwater and accurately measure constituent concentrations in the water samples [40 CFR 257.93(b)]. Some state agencies require EPA sanctioned analytical methods. **Appendix C** lists many of the laboratory analytical methods used at our laboratories. Also listed is the type of sample container needed, the preservative, the holding time, and the name of the method.

The laboratory reports will be prepared in accordance with the laboratory's quality assurance procedures. The laboratories accreditation organization, e.g., NELAC, and the analytical method may also have reporting requirements.

2.4 Quality Assurance and Quality Control

Field quality assurance

Field quality control measures are proven procedures for collecting representative samples, calibrating field testing equipment, preserving samples for analysis, and documenting chain of custody. These measures contribute to producing monitoring results that are reliable indications of groundwater quality.

Calibration of field instruments

The instruments will be calibrated in accordance with the manufacturer's instructions. A record of the calibration procedures used and information on the specific standards used should be recorded on the Calibration Record Form or a similar form. At a minimum, a notation will be made stating that each instrument is in calibration or not in calibration.

Quality control samples collected in the field

ACID BLANK OR PRESERVATIVE BLANK: The laboratory prepares an acid or preservative blank by filling a sample container with deionized water. The sampling technician adds the same preservative used for the groundwater sample to the blank sample container. Typically, nitric acid is the only preservative used. However, if another preservative is needed for a sample then a blank for that preservative will be prepared and used. One preservative blank is taken per sampling event per source container of preservative used. The laboratory analyzes the blank for the same constituents as the samples. This will demonstrate that the acid contains no contaminants or that it is contaminated with some of the constituents for which the sample is being analyzed.

If the laboratory provides the sample bottles with preservative already in them then a preservative blank sample will not be obtained.

FIELD DUPLICATE: A second sample collected as close as possible in space and time to an original sample. The original and duplicate samples are assigned different laboratory identification numbers and analyzed independently. The duplicate is typically identified with a code that does not enable the laboratory to correlate it to the original sample. The code and sample location are recorded on the groundwater sampling data form so that the analytical results from the duplicate can be compared to the original sample after laboratory analysis is complete. Duplicates are useful in documenting the precision of the sampling process. In groundwater monitoring, one field duplicate is commonly collected each day.

EQUIPMENT RINSATE: A sample of analyte-free media which has been used to rinse the reusable sampling equipment. It is collected after completion of decontamination and prior to sampling. This blank is useful in documenting adequate decontamination of sampling equipment. One equipment rinsate is typically collected per day, although additional rinsate samples may be collected if the sampler deems appropriate.

FIELD BLANK: In the field, analyte-free water is collected into a sample container with the same preservatives as used for the groundwater samples. The sample containers are the same lot as used for the groundwater samples. These samples are used to evaluate contamination introduced from the sample container(s) with applicable preservatives.

TRIP BLANK: A sample of analyte-free media taken from the laboratory to the sampling site and returned to the laboratory unopened. A trip blank is used to document contamination attributable to shipping and field handling procedures.

Laboratory quality assurance

The laboratory's quality assurance procedures are documented in the laboratory's quality assurance manual. The requirements of the quality assurance manual will be followed by the laboratory.

3. Well Development

Well development is not part of sampling and analysis. However, well development may take place during a sampling event. If well development is indicated as part of the sampling event, well development will take place after groundwater sampling for the particular well has been completed.

Well development is intended to remove fine particulate matter (turbidity), commonly clay and silt, from the geologic formation near the well intake. The groundwater is disturbed, suspending particulates into the groundwater, and the removing the groundwater with suspended particulates.

Two methods of well development will be used: surging and pumping.

Surging is performed with a surge block or device. The movement of the surge block causes the water to move in a turbulent manner inside the well. This water movement causes particulates to be suspended in the groundwater. The surge block should be of sufficient weight and density that when lowered it will force water out of the well and into the formation. The surge block should lifted quickly in order to cause turbulent flow into the well. After the groundwater has been agitated with the surging activity the monitoring well will be pumped to remove the turbid water. Repeated cycles of surging and pumping may occur if there is an adequate supply of groundwater and the activity results in the removal of particulates (turbidity).

Well development will be documented on the Well Development Record form.

Forms

Instructions to sampler for sampling event

Monitoring Well Construction Data

Groundwater Sampling Data Form

Calibration Record Form

Monitor Well Development Record

Well Inspection Form

Chain of Custody Form

Instructions to sampler for sampling event.

Location	Pirkey
Event	
Scheduled sample date	
Contact information	Control Room 903-927-5883 Samantha McDonald 903-927-5853 John Burgess 903-927-5887 Leslie Fuerschbach 318-673-2744; cell 318-464-3123
Number of wells to sample (CCR)	20
Number of duplicate samples needed including blanks (CCR)	1 -metal; 1 - WQ; 2 - Ra-226; 2 - Ra-228*
Number of wells to sample (State)	None. State samples are never taken at Pirkey.
Number of duplicate samples needed including blanks (State)	None
Parameters to sample (see lists of parameters below)	Appendix III and Appendix IV

CCR samples						
Well	Metals	WQ	Ra-226	Ra-228	Field parameters	Depth gauge
see list below	x	x	x	x	x	x
see list below						x
duplicates	1 per sampling day	1 per sampling day				
Ra duplicates - see below			x	x		
Equipment blank	1	1				

Monitoring wells

Monitoring wells to sample (CCR):AD-2, 3, 4, 7, 8, 12, 13, 16, 17, 18, 22, 23, 27, 28, 30, 31, 32, 33, 34, 36 (20 wells total)

Monitoring wells to gauge depth to water only: AD-10, 19, 20, 21, 25, 26, 29 (7 wells total)

Chain of Custody

There will be one chain of custody for CCR metals and water quality.
There will be one chain of custody for CCR radium samples.

Duplicate Samples

Duplicate samples for Ra-226 and Ra-228.

The Ra-226 and Ra-228 samples are two separate samples.
The TCEQ's CCR Rule requires the results of the two analyses (Ra-226 and Ra-228) to be combined mathematically and the combined result reported.

For the radium duplicates mark the well name on the sample label and mark it 'Laboratory QC duplicate'.

For the radium duplicates mark the well name on the sample label and mark it 'Laboratory QC duplicate'.
The sample and duplicate for Ra-226 may come from a different well than the sample and duplicate for Ra-228.

The sample for Ra-226 will be one 1 liter bottle. The sample for Ra-228 will be one 1 liter bottle.
For every 10 wells or less obtain 1 duplicate for Ra-226.
*For every 10 wells or less obtain 1 duplicate for Ra-228 - however the duplicate will require 2 - 1 liter bottles.

Other duplicates.

Sample Bottles

Sample bottles and preservatives needed for each well:

CCR:
If Appendix III only is being sampled then one - 500 mL plastic for metals (nitric acid preservative) and one - 1 Liter plastic for water quality (ice sample to preserve).

If Appendix IV only is being sampled then one - 500 mL plastic for metals (nitric acid), one 1 Liter plastic for Ra-226 (nitric acid), one - 1 Liter plastic for Ra-228 (nitric acid), and one - 1 Liter plastic for water quality (ice).

If both Appendix III and Appendix IV are being sampled then one - 500 mL plastic for metals (nitric acid), one - 1 Liter plastic for Ra-226 (nitric acid), one - 1 Liter plastic for Ra-228 (nitric acid), and one - 1 Liter plastic for water quality (ice).

NOTE:
The metals sample bottle will provide groundwater for: Sb, As, B, Ba, Be, Ca, Cd, Cr, Co, Pb, Li, Hg, Mo, Se, Tl.
The water quality sample bottle will provide groundwater for: chloride, fluoride, sulfate, TDS.

Parameters

Appendix III parameters
Boron (B)
Calcium (Ca)
Chloride (Cl-)
Fluoride (F-)
pH
Sulfate (SO4-)
Total Dissolved Solids

Appendix IV parameters
Antimony (Sb)
Arsenic (As)
Barium (Ba)
Beryllium (Be)
Cadmium (Cd)
Chromium(Cr)
Cobalt(Co)
Fluoride (F-)
Lead (Pb)
Lithium(Li)
Mercury (Hg)
Molybdenum (Mo)
Selenium (Se)
Thallium (Tl)
Radium 226 and 228 combined (Ra)

NOTE: pH is measured in the field. A lab sample for pH is not obtained.

APPENDIX C

Laboratory Analysis Methods, Sample Containers, and Preservation Protocols

Cooling is not prohibited unless specifically noted. Cooling is required if specified for the analyte.

Analyte	**Metals -** aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, molybdenum, nickel, selenium, silver, strontium, thallium, tin, vanadium, zinc	
Method	EPA 200.7	Method 6010B
Container	plastic; glass (not acceptable for boron); perfluoropolymer	
Preservation	HNO_3 to pH<2	
Hold time	180 days	

Analyte	**Mercury**	
Method	EPA 7470A	EPA 245.1
Container	plastic; glass; perfluoropolymer	
Preservation	Hydrochloric to pH<2 (EPA 245.7); HNO_3 to pH<2 (EPA 7470)	
Hold time	28 days	

Analyte	**Chloride**
Method	EPA 300.0
Container	plastic; glass; perfluoropolymer
Preservation	None required
Hold time	28 days

Analyte	**Fluoride**
Method	EPA 300.0
Container	plastic; glass; perfluoropolymer
Preservation	None required
Hold time	28 days

Analyte	**Sulfate**
Method	EPA 300.0
Container	plastic; glass; perfluoropolymer
Preservation	cool, ≤ 6^{o}C
Hold time	28 days

Analyte	**Solids, total dissolved (TDS)**
Method	SM 2540 C
Container	plastic; glass; perfluoropolymer
Preservation	cool, ≤ 6^{o}C
Hold time	7 days

Analyte	**Radium 226**
Method	Method 9315
Container	plastic; glass; perfluoropolymer
Preservation	HNO_3 to pH<2
Hold time	180 days

Analyte	**Radium 228**
Method	Method 9320
Container	plastic; glass; perfluoropolymer
Preservation	HNO_3 to pH<2
Hold time	180 days

Analyte	**Ra-226 and Ra-228 combined**
Method	The TCEQ's CCR Rule in Appendix IV refers to 'Radium 226 and 228 combined'. The drinking water MCL is 5 pCi/L for Radium 226 and 228 combined. However, for laboratory analysis, there are two separate tests. The laboratory performs two analysis - one for Ra-226 and another for Ra-228. The value for Radium 226 and 228 combined is the arithmetic sum of the results for these two tests.

SECTION 1

INTRODUCTION

In June 2021, the Texas Commission on Environmental Quality (TCEQ) issued new regulations regarding the disposal of coal combustion residuals (CCR) in certain landfills and impoundments under Title 30, Chapter 352, "Coal Combustion Residuals Waste Management." This Chapter is referred to herein as the "CCR rules." Facilities regulated under the CCR rules are required to develop and sample a groundwater monitoring well network to evaluate if landfilled CCR materials are impacting downgradient groundwater quality. As part of the evaluation, the analytical data collected during the sampling events must undergo statistical analysis to identify statistically significant increases (SSIs) in analyte concentrations above background levels. A description of acceptable statistical programs is provided in USEPA's document *Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities*, *Unified Guidance* (USEPA, 2009), which is commonly referred to as the "Unified Guidance."

The CCR rules are not prescriptive regarding what statistical analyses should be selected so that groundwater data are interpreted in a consistent manner and the results meet certification requirements. Geosyntec Consultants, Inc. (Geosyntec) prepared this Statistical Analysis Plan (SAP) on behalf of American Electric Power (AEP) to develop a logic process regarding the appropriate statistical analysis of groundwater data collected in compliance with the CCR rules. The SAP will provide a narrative description of the statistical approach and methods used in accordance with the CCR rule reporting requirements [30 TAC 352.931].

This SAP describes statistical procedures to be used to establish background conditions, implement detection monitoring, implement assessment monitoring (as needed), and implement corrective action monitoring (as needed) for the H.W. Pirkey Power Plant East Bottom Ash Pond (EBAP), West Bottom Ash Pond (WBAP), Flue Gas Desulfurization (FGD) Stackout Area, and Landfill, all of which are located in Hallsville, Texas.

Procedures for collecting, preserving, and shipping groundwater samples are not included in this SAP. It is assumed that samples are collected and handled in accordance with AEP's statistical analysis plan and the requirements of 30 TAC 352.901 *et seq*.

SECTION 2

ANALYSES FOR REVIEWING AND PREPARING DATA

2.1 Physical Independence

Most statistical analyses require separate sampling events to be statistically independent. Statistical independence of groundwater samples is most likely to be realized when the samples are collected at time intervals that are sufficiently far apart that the samples are not from the same volume of groundwater. In such cases, the samples of groundwater are considered physically independent. To ensure physical independence, the minimum time between sampling events must be longer than the residence time of groundwater that would be collected in the monitoring well. The minimum time interval between sampling events (t_{min}) can be determined by calculating the groundwater velocity, as follows:

$$v = \frac{Ki}{n} \quad (1)$$

$$t_{min} = \frac{v}{D} \quad (2)$$

where:

$v =$ groundwater velocity
$K =$ hydraulic conductivity
$i =$ hydraulic gradient
$n =$ effective porosity
$t_{min} =$ minimum time interval between sampling events
$D =$ well bore volume (i.e., diameter of well and surrounding filter pack)

2.2 Testing for Normality

Many statistical analyses assume that the sample data are normally distributed. If such an analysis is used, the assumption of normality can be tested using the Shapiro-Wilk test (for sample sizes up to 50) or the Shapiro-Francía test (for sample sizes greater than 50). Normality can also be tested by less computationally intensive means such as graphing data on a probability plot. If the data appear not to be normally distributed (e.g., they are skewed in some fashion), then data may be transformed mathematically such that the transformed data do follow a normal distribution (e.g., lognormal distributions, Box-Cox transformations). Alternatively, a non-parametric test (i.e., a test that does not assume a particular distribution of the data) may be used. However, since non-parametric tests generally require large datasets to maintain an adequately low site-wide false positive rate (SWFPR), transforming the data is preferred.

2.3 Testing for Outliers

Outliers are extreme data points that may represent an anomaly or error. Datasets should be visually inspected for outliers using time series and/or box-and-whisker plots. While they are valuable as screening tools, visual methods are not foolproof. For example, if data are skewed according to a lognormal distribution, the boxplot screening may identify more outliers than actually exist. Typically, goodness-of-fit testing must be done on the non-outlier portion of the data to determine at what scale to test the possible outliers.

Potential outliers should be evaluated for potential sources of error (e.g., in transcription or calculation) or evidence that the data point is not representative (e.g., by examining quality control [QC] data, groundwater geochemistry, sampling procedures, etc.). Errors should be corrected prior to further statistical analysis, and data points that are flagged as non-representative should not be used in the statistical analysis. In addition, data points can be considered extreme outliers if they meet one of the following criteria:

$$x_i < \tilde{x}_{0.25} - 3 \times IQR \quad (3)$$

or

$$x_i > \tilde{x}_{0.75} + 3 \times IQR \quad (4)$$

where:

$x_i =$ individual data point
$\tilde{x}_{0.25} =$ first quartile
$\tilde{x}_{0.75} =$ third quartile
$IQR =$ the interquartile range $= \tilde{x}_{0.75} - \tilde{x}_{0.25}$

Extreme outliers may be excluded from the statistical analysis based on professional judgment. Goodness-of-fit testing may be needed to corroborate the classification of data points as extreme outliers. Flagged data and extreme outliers should still be maintained in the database and should be reevaluated as new data are collected.

2.4 Handling Duplicate or Replicate Data

Duplicate or replicate samples are often collected for QC purposes. Averaging the parent sample and duplicate sample results may give a more accurate representation of the constituent concentration at the time, but doing so would reduce the sample variability. Since many statistical tests assume that data are homoscedastic (i.e., the population variance does not change across samples), this technique is not recommended. Unless there is reason to suspect that either the parent sample or the duplicate sample is more representative of site groundwater, one of the samples should be selected at random and that value should be used in the subsequent statistical analysis. However, it should be reported when parent sample and duplicate sample results are different from a decision-making perspective, e.g., when the duplicate sample exceeds the groundwater protection standard (GWPS) but the parent sample does not.

2.5 Handling Non-Detect Data

If non-detect data are infrequent (less than 15%), half of the reporting limit (RL) can be used in place of these data without significantly altering the results of a statistical test. The RL may be either the laboratory practical quantification limit (PQL) or an established project limit which is less than the maximum contaminant level (MCL). If non-detect data are more frequent, parametric methods that explicitly consider non-detects or non-parametric methods insensitive to the presence of non-detect data should be used. Where available, estimated results less than the RL (i.e., “J-flagged” data) should be used, and these data should be considered detections for the purposes of statistical analysis.

2.6 Deseasonalizing Data

Most statistical tests assume that data are independent and identically distributed. Datasets with seasonal or cyclic patterns violate this assumption. If seasonal trends are not corrected, the variance of the data will be overestimated, lessening the statistical power of the test. False positives may also be identified for elevated results that are caused by seasonal variation instead of a release.

At the same time, deseasonalizing data inherently assumes that the seasonal pattern will continue into the future, so care should be taken when correcting for seasonality. There should be a physical explanation for the seasonal pattern, and the seasonal pattern should be observed for at least three cycles before deseasonalizing data.

To evaluate whether a seasonal pattern exists, data should first be visually inspected on a time series plot. Observing parallel or antiparallel patterns for the same constituent across multiple wells or for multiple constituents within a single well provides greater assurance of a seasonal pattern and may be used to infer a physical explanation.

If a seasonal pattern is observed, the dataset should undergo a statistical test for seasonality before deseasonalizing the data. First, results are categorized into seasons based on the observed seasonal pattern and the frequency of sampling (e.g., summer or winter; dry season or wet season; first, second, third, or fourth quarter; etc.). Then, the Kruskal-Wallis test can be applied to the various seasonal datasets to test whether the different seasons are statistically significantly different from one another.

To deseasonalize the data, a seasonal mean should be calculated for each season based on the categorization for the dataset, and a grand mean (i.e., the overall mean of all data) should be calculated. Each result should then be corrected based on the difference between the grand mean and the seasonal mean for that result’s season. Similar to transforming apparently non-normal data, statistics should be calculated based on the deseasonalized data.

SECTION 3

DETECTION MONITORING

3.1 Establishing Background

By October 17, 2017, eight independent background samples should be collected from each monitoring well in the CCR unit groundwater monitoring system as part of the initial monitoring period [30 TAC 352.941(a)]. Background wells do not necessarily need to be hydraulically upgradient of the CCR unit, but they must not be affected by a release from the CCR unit [30 TAC 352.911(a)]. The sampling frequency should be such that samples are physically independent, as described in **Section 2.1**. Samples should be analyzed for the Appendix III and Appendix IV constituents listed in **Table 1**.

Once analytical data are received, summary statistics (e.g., mean and variance) should be calculated for the background datasets. Initially, analysis should be done independently for each constituent at each well. As part of our protocol in such situations, time series plots and box plots will be prepared along with the summary statistics. The Kaplan-Meier method or robust regression on order statistics (ROS) can be used to compute summary statistics when there are large fractions (i.e., 15% to 50%) of non-detects; these methods are discussed below. If more than 50% of the data are non-detect, then summary statistics cannot be reliably calculated. Procedures for evaluating future data against these background datasets are described in **Section 3.2.1** (for detection monitoring) and **Section 4.1.1** (for assessment monitoring and corrective action monitoring).

Background data will be evaluated for statistically significant temporal trends using (a) ordinary least-squares (OLS) linear regression with a *t*-test ($\alpha = 0.01$) on the slope and/or (b) the non-parametric Theil-Sen slope estimator with Mann-Kendall trend test ($\alpha = 0.05$, or 0.01 for larger datasets). Non-detect data are replaced with half the RL for these analyses. The OLS linear regression or Theil-Sen slope estimator will be used to estimate the rate of change (increasing, no change, or decreasing) over time for each constituent at each well. The *t*-test or Mann-Kendall statistic will be used to determine whether a trend is statistically significant. OLS linear regression should only be used when at most 15% of the data are non-detect, when regression residuals are normally distributed, and when the variance from the regression line does not change over time. The Theil-Sen/Mann-Kendall analysis requires at least five observations for meaningful results; at least eight observations are recommended. Note that a statistically significant increasing trend in background data (or a statistically significant decreasing trend in pH) could indicate an existing release from the CCR unit or another source, and further investigation may be needed to determine the source of this trend.

Background data will also be evaluated for statistically significant seasonal patterns and, if present, will be deseasonalized using the procedure described in **Section 2.6**.

If the trend analysis does not indicate a statistically significant trend, the proposed background data will be tested for normality using one of the methods outlined in **Section 2.2**. When data follow a normal or transformed-normal distribution (e.g. lognormal or other Box-Cox transformation), parametric methods are applied. If fewer than 15% of the data are non-detect, non-detect data may be replaced with half the RL and the mean and variance can be calculated normally. If 15% to 50% of the data are non-detect, two methods – the Kaplan-Meier or Robust ROS method – can be used to determine the sample mean and variance. Kaplan-Meier should not be used if all non-detect data have the same RL or if the maximum detected value is less than the highest RL of the non-detect data. When data do not follow a normal or transformed-normal distribution, or when more than 50% of the data are non-detect, nonparametric methods may be used.

Once the sample mean and variance are calculated for each constituent at each well (assuming no significant trends over time), the data from background wells should be compared for each constituent. The purpose of this exercise is to test for significant spatial variation and to decide between interwell and intrawell approaches. First, the equality of variance across background wells should be tested visually using box-and-whisker plots and/or analytically using Levene's test ($\alpha = 0.01$). If the variances appear equal, then one-way, parametric analysis of variance (ANOVA) should be conducted across background wells ($\alpha = 0.05$). If there are no statistically significant differences among the background wells, then interwell comparisons may be appropriate to evaluate SSIs.

If ANOVA indicates statistically significant differences among background wells, then spatial variability can be concluded. As with temporal trends, the existence of spatial variability could indicate an existing release from the CCR unit or another source, and further investigation may be needed to determine the source of this variability. If the spatial variability is not caused by a release from the CCR unit, then intrawell comparisons would be appropriate to evaluate SSIs.

3.2 Evaluating Statistically Significant Increases (SSIs)

After the initial eight rounds of background sampling, groundwater sampling and analysis should be conducted on a semiannual basis. The statistical evaluation of each groundwater monitoring event must be completed within 90 days of receiving the analytical results from the laboratory [30 TAC 352.931(a)].

The CCR rules only require analysis of the Appendix III constituents; however, analyzing additional constituents should be considered. Turbidity, dissolved oxygen, and oxidation-reduction potential (ORP), should be measured in the field in addition to pH. Other geochemical parameters, such as alkalinity, magnesium, potassium, sodium, iron, and manganese, should also be analyzed in the laboratory periodically (e.g., once every one to four years). Both the field and laboratory geochemical parameters can help identify the cause of any apparent change in groundwater quality. Additionally, analyzing for the Appendix IV constituents periodically should be considered to ensure the background dataset for these constituents is complete and current should assessment monitoring be needed. Statistical analyses should still be limited to the Appendix III constituents to help meet the dual goals of a SWFPR less than 10% per year and an adequate statistical power.

The CCR rules specifically list four methods acceptable for statistical analysis: ANOVA, tolerance intervals, prediction intervals, and control charts [30 TAC 352.931(a)]. Of these, the Unified Guidance recommends prediction limits combined with retesting for maintaining a low SWFPR while providing high statistical power (USEPA, 2009). Control charts are also acceptable as long as parametric methods can be used (i.e., the data or transformed data are normally distributed and the frequency of non-detects is at most 50%), as there is no nonparametric counterpart to the control chart. ANOVA is not recommended as the CCR rules mandate a minimum Type I error (α) of 0.05, at which it would be difficult to maintain an annual SWFPR less than 10%.

Prediction intervals and control charts can be used for both interwell and intrawell comparisons. For interwell comparisons, the pooled data from background monitoring wells should be used for the background dataset; for intrawell comparisons, the background dataset should be a subset of historical data at each monitoring well. (See **Section 3.4** below for procedures for updating background datasets.) Interwell comparisons are preferable, but they should only be used when there are no trends and no statistically significant population differences among background wells; otherwise, a significant test result may only indicate natural spatial variability instead of an SSI.

For prediction intervals, the upper prediction limit (UPL) is calculated according to the following formula:

$$\mathrm{UPL} = \bar{x} + ks \quad (5)$$

where:

$\bar{x} =$ mean concentration of the background dataset
$s =$ standard deviation of the background dataset
$k =$ multiplier based on the characteristics of the site and the statistical test

Values for k are chosen to maintain an SWFPR less than 10% and depend on the following: (1) number of wells, (2) number of constituents being evaluated, (3) size of the background dataset, (4) retesting regime, and (5) whether intrawell or interwell comparisons are being used. Values for k are listed in Tables 19-1, 19-2, 19-10, and 19-11 in Appendix D of the Unified Guidance (USEPA, 2009). If the k value that precisely matches site conditions does not appear in these tables, it can be estimated using the provided values by linear interpolation.

A one-of-two or one-of-three testing regime should be employed; i.e., if at least one sample in a series of two or three (respectively) does not exceed the UPL, then it can be concluded that an SSI has not occurred. In practice, if the initial result does not exceed the UPL, then no resampling is needed. If the initial result does exceed the UPL, then a resample should be collected prior to the next regularly scheduled sampling event at the monitoring well(s) and for the constituent(s) exceeding the UPL. Additional geochemical parameters, such as alkalinity, magnesium, potassium, sodium, iron, and manganese, should also be analyzed during resampling to help identify the source of the apparent increase. Enough time should elapse between the initial sample and each resample so that the samples are physically independent (**Section 2.1**). If both the initial result and the subsequent resample(s) exceed the UPL, then an SSI can be concluded.

Choosing between a one-of-two and a one-of-three testing regime should be done before conducting the statistical analysis, as the UPL calculation depends on the resampling regime selected. The choice should depend on site conditions and the size of the background dataset. First, if three physically independent samples cannot be collected in a six-month period, then a one-of-two testing regime should be used. A one-of-two testing regime may also be considered (a) if the background dataset has at least 16 data points or (b) if the CCR unit's monitoring well network has nine or fewer downgradient monitoring wells and a background dataset of at least 8 data points. Otherwise, a one-of-three testing regime should be employed to achieve an acceptably high statistical power and an acceptably low SWFPR.

If two physically independent samples cannot be collected in a six-month period, then a reduced monitoring frequency may be warranted. In this case, a demonstration must be made documenting the need for – and effectiveness of – a reduced monitoring frequency. This demonstration must be certified by a qualified professional engineer, and monitoring must still be done on at least an annual basis [30 TAC 352.941(a)].

The above procedure can be used wherever a mean and variance can be calculated for background data, including datasets that are transformed-normal and datasets where the mean and variance are calculated using the Kaplan-Meier or Robust ROS method. (Note that if data are transformed-normal, prediction intervals or control limits should first be calculated for the transformed data and then be transformed back into concentration terms.) Methods for determining prediction intervals where more than half of the background data are non-detect, where background data are neither normal nor transformed-normal, or where statistically significant trends or seasonal patterns exist are described below.

Different analyses can and should be used for different constituents and different monitoring wells within a CCR unit depending on the background data. For instance, if background wells have similar chloride data but different pH data, then interwell comparisons may be considered for chloride analysis and intrawell comparisons may be considered for pH analysis. If boron data are stable above the RL at MW-1 and mostly non-detect at MW-2, then it would be appropriate to use parametric prediction limits at MW-1 and non-parametric prediction limits at MW-2.

3.2.1 Most Background Data Are Non-Detect

If at least half of the data are non-detect, non-parametric prediction intervals with retesting should be used. In this method, the UPL is set either at the highest or at the second-highest concentration observed in the background dataset. A sufficiently large background dataset is paramount for this procedure to achieve an acceptably low SWFPR. To this end, the Kruskal-Wallis test should be performed on all background monitoring wells where at least 50% of the data for the constituent are non-detect to evaluate spatial variability. If the Kruskal-Wallis test indicates that there is no significant spatial variability among background wells, then the data from the background wells should be pooled to form a larger background dataset and thus to run an interwell test.

The choice between a one-of-two and a one-of-three testing regime should be based on the same criteria used for parametric testing, as described in **Section 3.2**. Choosing between using the highest or second-highest observed concentration as the UPL should depend in part on the size of the background dataset and the number of monitoring wells around the CCR unit. Assuming a one-of-three testing regime is used, the highest observed concentration should be used when the background dataset has fewer than 32 data points and the monitoring network has twelve or fewer wells. If there are at least thirteen wells, the highest observed concentration should be used when the background dataset has fewer than 48 data points. The second-highest observed concentration may be used for larger datasets.

If a one-of-two testing regime must be used due to aquifer conditions, then the highest observed concentration should be used (a) when the background dataset has fewer than 64 data points if there are fifteen or fewer wells or (b) when the background dataset has fewer than 88 data points if there are at least sixteen wells. The second-highest observed concentration may be used for larger datasets.

3.2.2 All Background Data Are Non-Detect

If all of the background data are non-detect, then the Double Quantification Rule should be used. According to this rule, if a sample and verification resample both exceed the PQL, then an SSI can be concluded. This can be thought of as setting the UPL at the PQL with a one-of-two testing regime. The possibility of false positives from this rule does not count against the calculated SWFPR because the false positive risk is small when all previous background data have been non-detect.

3.2.3 Background Data Are neither Normal nor Transformed-Normal

If background data are non-normal and cannot be transformed such that the transformed data do follow a normal distribution, then non-parametric prediction intervals with retesting should be used. In this method, the UPL is set either at the highest or at the second-highest concentration observed in the background dataset. A sufficiently large background dataset is paramount for this procedure to achieve an acceptably low SWFPR. To this end, the Kruskal-Wallis test should be performed on all background monitoring wells where at least 50% of the data for the constituent are non-detect to evaluate spatial variability. If the Kruskal-Wallis test indicates that there is no significant spatial variability among background wells, then the data from the background wells should be pooled to form a larger background dataset and thus to run an interwell test.

The choice between a one-of-two and a one-of-three testing regime should be based on the same criteria used for parametric testing, as described in **Section 3.2**. The choice between using the highest or second-highest observed concentration as the UPL should be based on the same considerations described in **Section 3.2.1**.

3.2.4 A Significant Temporal Trend Exists

True temporal trends in background data (i.e., absent a release from the facility or another source) are considered unlikely. Thus, a truncated dataset that does not exhibit a statistically significant trend may be used. In these cases, UPLs would be calculated as described in the previous sections.

Alternatively, if there is a significant temporal trend in the background data that is not attributable to a release, prediction limits can be constructed around a trend line. A trend line can be constructed parametrically using OLS linear regression. OLS linear regression should only be used when at most 15% of the data are non-detect, when regression residuals are normally distributed, and when the variance from the regression line does not change over time. If OLS linear regression is used, the UPL can be calculated according to the following equation:

$$\text{UPL} = \widehat{x_0} + t_{1-\alpha,n-2} * s_e * \sqrt{1 + \frac{1}{n} + \frac{(t_0 - \bar{t})^2}{(n-1)s_t^2}} \quad (6)$$

where:

$\widehat{x_0} =$ regression-line estimate of the mean concentration at time t_0
$t_{1-\alpha,n-2} =$ one-tailed *t*-value at a confidence of 1 – α and n – 2 degrees of freedom
$s_e =$ standard error of the regression line
$n =$ number of samples in the background dataset
$t_0 =$ date the groundwater sample being compared to the UPL was collected
$\bar{t} =$ mean of the sampling dates in the background dataset
$s_t =$ standard deviation of the sampling dates in the background dataset

The choice between a one-of-two and a one-of-three testing regime should be based on the same criteria used when there is no significant trend, as described in **Section 3.2**. The choice of α depends on the retesting regime and the number of wells within the monitoring network. If a one-of-two testing regime is employed, an α = 0.02 is recommended if there are eighteen or fewer wells and an α = 0.01 is recommended if there are at least nineteen wells within the monitoring network. If a one-of-three testing regime is employed, an α = 0.05 should be used.

3.2.5 A Significant Seasonal Pattern Exists

If a statistically significant seasonal pattern exists and if there is a physical explanation for the seasonality, the background data should be deseasonalized using the procedure described in **Section 2.6**. The background UPL should be calculated based on the deseasonalized data. Results should then be deseasonalized by subtracting the difference between the seasonal mean and the grand mean before comparing results to the UPL.

3.3 Responding to an Identified SSI

If the statistical evaluation indicates that an SSI is present, TCEQ and any local pollution agencies with jurisdiction that had requested to be notified should be notified in writing within 14 days of the SSI determination [30 TAC 352.941(b)] and intention to make an alternative source demonstration [30 TAC 352.941(c)(1)]. The data should be evaluated to assess whether the SSI is caused by a release from the CCR unit. If it can be shown that the SSI resulted from a release from another source, from an error in sampling or analysis, or from natural variability, then a demonstration of this must be made in writing and certified by a qualified professional engineer within 90 days of completing the statistical evaluation [30 TAC 352.941(c)(2)]. (The statistical evaluation itself must be completed within 90 days of receiving the analytical data from the laboratory.) If this demonstration is not made within 90 days of completing the statistical evaluation or was not satisfactory to TCEQ, then the site must begin assessment monitoring [30 TAC 352.941(d)].

3.4 Updating Background

As recommended in the Unified Guidance, background values should be updated every four to eight measurements, assuming no confirmed SSI is identified (USEPA, 2009). (See **Section 4.4** for procedures for updating background if an SSI has been identified.) A Student's *t*-test or the nonparametric Mann-Whitney test (also known as the Wilcoxon rank-sum test) should be conducted to compare the set of new data points against the existing background dataset, as appropriate. An $\alpha = 0.05$ is recommended given the relatively small size of the datasets, particularly if background is updated every four measurements and particularly if the nonparametric Mann-Whitney test is used. However, an α as low as 0.01 may be used if the existing background dataset is sufficiently large (i.e., contains at least five data points) or if Student's *t*-test is used.

If the *t*-test or Mann-Whitney test does not indicate significant differences, the new data should be combined with the existing background data to calculate an updated UPL. Increasing the size of the background dataset will increase the power of subsequent statistical tests.

If the *t*-test or Mann-Whitney test indicates a statistically significant difference between the two populations, then the data should not be combined with the existing background data until further review determines the cause of the difference. If the differences appear to be caused by a release, then the previous background dataset should continue to be used. Absent evidence of a release, the new dataset should be considered more representative of present-day groundwater conditions and used for background. Note that the *t*-test or Mann-Whitney test is used to compare new data to the existing background dataset for the purposes of updating background. The tests are not used to determine whether an SSI is present or whether a release has occurred.

Periodically, spatial variability among background wells may be re-assessed to determine whether using an interwell or intrawell comparison is appropriate on a constituent-by-constituent basis, as outlined in **Section 3.1**.

SECTION 4

ASSESSMENT MONITORING

A CCR unit must begin assessment monitoring if an SSI is identified and is not attributed to some cause besides a release from the CCR unit. Assessment monitoring must begin within 90 days of identifying the SSI. During this 90-day period, the monitoring well network must be sampled for all Appendix IV constituents [30 TAC 352.951(a)]. Within 90 days of obtaining the results from this sampling event, all of the CCR unit wells must be sampled for all Appendix III constituents and those Appendix IV constituents that were detected during the initial assessment monitoring event [30 TAC 352.951(a)].

After these initial assessment monitoring events, the CCR unit wells must be sampled for all Appendix III constituents and previously detected Appendix IV constituents on a semiannual basis [30 TAC 352.951(a)]. Additionally, the CCR unit wells must be sampled for all Appendix IV constituents on an annual basis [30 TAC 352.951(a)].

As with detection monitoring, if physically independent samples cannot be collected on a semiannual basis, then a reduced monitoring frequency may be warranted. A demonstration must be made documenting the need for – and effectiveness of – a reduced monitoring frequency. This demonstration must be certified by a qualified professional engineer, and monitoring must still be done on at least an annual basis [30 TAC 352.951(a)].

GWPSs must be established for each detected Appendix IV constituent. The GWPS shall be the greater of the background concentration and the MCL established by the USEPA for that constituent [30 TAC 352.951(b)]. If no MCL exists for that constituent, then the background concentration shall be the GWPS for that constituent [30 TAC 352.951(b)(2)]. An upper tolerance limit (UTL) with 95% confidence and 95% coverage is often used as the representative background concentration.

A single site-wide GWPS would be recommended for each constituent based on pooled background data, even if natural spatial variability exists. If background data are not pooled, background concentrations and consequently GWPSs would vary from well to well. One difficulty with this approach is that concentrations at one monitoring well may exceed the location-specific GWPS and still be below levels considered as natural background at other locations within the site. The pooled background is often more interpretable and less cumbersome for developing a single background-based GWPS per constituent.

To determine whether a move to corrective action is warranted, a confidence interval constructed on recent data at each compliance monitoring well should be compared to the site-wide GWPS. When the lower confidence limit (LCL) of this interval exceeds the GWPS, an assessment of corrective measures may be justified.

When corrective action is not warranted, to return from assessment monitoring to detection monitoring, the CCR rules specify that all Appendix III and IV constituents must be at or below background levels for two consecutive sampling events and after written approval from TCEQ [30 TAC 352.951(c)]. Procedures for comparing results to background are described in **Section 4.2**.

4.1 Comparing Data to the GWPS

As stated in **Section 4**, the GWPS is set at the MCL or (if an MCL does not exist for that constituent or if background data are higher than the MCL) a value based on background data, whichever is greater. The UTL calculated from the background dataset is often used as the background value.

Tolerance intervals are similar to prediction intervals. However, whereas prediction intervals represent a range where a future result is expected to lie, tolerance intervals represent a range where a proportion of the population is expected to lie. Tolerance intervals have both an associated coverage (i.e., the proportion of the population covered by the tolerance interval) and an associated confidence. A coverage of 95% ($\gamma = 0.95$) and a confidence of 95% ($\alpha = 0.05$) are typically used.

The UTL is calculated similarly to the UPL:

$$\mathrm{UTL} = \bar{x} + \tau s \quad (7)$$

Similar to the UPL calculation, $\bar{x}$ is the mean concentration and s is the standard deviation of the background dataset. However, in this case the multiplier τ is different from that of the UPL calculation and is a function of the chosen coverage and confidence and the size of the background dataset. Values of τ are tabulated in Table 17-3 in Appendix D of the Unified Guidance (USEPA, 2009). As with prediction limits, if the τ value that precisely matches site conditions does not appear in these tables, it can be estimated using the provided values by linear interpolation.

Once a GWPS is established, new data must be evaluated to determine whether they are statistically significantly higher than the GWPS. The statistical analyses listed in 40 CFR 257.93(f), as included by reference in 30 TAC 352.931(a), are appropriate for comparing new data to a background dataset but are not appropriate for comparing new data to a fixed standard. For these cases, the Unified Guidance recommends using confidence intervals around the mean or median (USEPA, 2009).

Evaluations should be done for each detected Appendix IV constituent at each well. Data from different wells should not be pooled. When selecting which data to include in the recent dataset, time series plots of concentration data at each well should be created and visually inspected. Only data that exhibit the same behavior as recent data should be included. For instance, if the last eight arsenic results cluster around 9 μg/L and the previous eight results cluster around 4 μg/L, then only the eight most recent results should be used in the statistical analysis. Similarly, if chromium concentrations steadily increased over the last ten samples and were stable previously, then the statistical analysis should only use the ten most recent results and (since they are steadily increasing) should involve constructing a confidence interval around a trend line.

At the same time, datasets should also be sufficiently large to maintain statistical power. As many data points that exhibit the same behavior as recent data as possible should be included, including data collected prior to assessment monitoring (e.g., during the initial eight monitoring events). Ideally, datasets should have at least eight data points; in no case should a dataset have fewer than four data points.

If at least 50% of the recent dataset is non-detect, then a parametric confidence interval should not be used, and the procedure in **Section 4.1.1** should be followed.

New data will be evaluated for statistically significant temporal trends using (1) OLS linear regression with a *t*-test ($\alpha = 0.01$) on the slope and/or (2) the non-parametric Theil-Sen slope estimator with Mann-Kendall trend test ($\alpha = 0.05$, or 0.01 for larger datasets). Non-detect data are replaced with half the RL for these analyses. The OLS linear regression or Theil-Sen slope estimator will be used to estimate the rate of change (increasing, no change, or decreasing) over time for each constituent at each well. The *t*-test or Mann-Kendall statistic will be used to determine whether a trend is statistically significant. OLS linear regression should only be used when at most 15% of the data are non-detect, when regression residuals are normally distributed, and when the variance from the regression line does not change over time. The Theil-Sen/Mann-Kendall analysis requires at least five observations for meaningful results; at least eight observations are recommended. If a significant temporal trend exists, then a confidence interval around the trend line should be constructed as outlined in **Section 4.1.3**.

If the trend analysis does not indicate a statistically significant trend, then the mean and variance should be calculated. If fewer than 15% of the data are non-detect, then the non-detect data can be replaced with half the RL and the mean and variance can be calculated normally. Tolerance intervals are sensitive to the choice of population distribution. Normality should be confirmed using the Shapiro-Wilk (or Shapiro-Francía) test and/or probability plots, as described in **Section 2.2**. If data appear not to be normally distributed, data should be transformed so that the transformed data are normally distributed.

Two methods – the Kaplan-Meier or Robust ROS method – can be used to determine the sample mean and variance when 15% to 50% of the data are non-detect. Kaplan-Meier should not be used if all non-detect data have the same RL or if the maximum detected value is less than the highest RL of the non-detect data.

When most of the data are detections, data are normally distributed, and there is no significant temporal trend, the LCL is calculated according to the following equation:

$$\mathrm{LCL} = \bar{x} - t_{1-\alpha,n-1} * \frac{s}{\sqrt{n}} \quad (8)$$

where:

$\bar{x} =$ mean concentration of the recent dataset
$t_{1-\alpha,n-1} =$ one-tailed t-value at a confidence of 1 – α and at n – 1 degrees of freedom
$s =$ standard deviation of the recent dataset
$n =$ number of samples in the recent dataset

The *t* value must be chosen in such a way to balance the competing goals of a low false-positive rate and a high statistical power. The Unified Guidance recommends that the statistical test have at least 80% power ($1 - \beta = 0.8$) when the underlying mean concentration is twice the MCL (USEPA, 2009). Values of the minimum α (from which *t* values can be determined) are tabulated for this criterion for various values of *n* in Table 22-2 in Appendix D of the Unified Guidance (USEPA, 2009). The selected α should be the maximum of the value in Table 22-2 and 0.01.

If data are transformed normal, the LCL should first be calculated for the transformed data and then be transformed back into concentration terms. Correction factors are available but are not expected to be required. Alternatively, a non-parametric LCL can be used, as described in **Section 4.1.2**.

If data are non-normal and cannot be transformed such that the transformed data do follow a normal distribution, then a non-parametric LCL should be used, as described in **Section 4.1.2**.

If the LCL exceeds the GWPS, then a statistically significant exceedance can be concluded. If this occurs, the owner/operator is required to take several actions, including potentially moving the facility to corrective action, as described in **Section 4.3**.

4.1.1 Most Data Are Non-Detect

If background data are mostly non-detect, non-parametric tolerance intervals should be used. In these cases, the UTL is set at either the highest or second-highest concentration observed in the background dataset. If all background data are non-detect, then the UTL would default to the RL. The highest or second-highest observed concentration (or RL) effectively becomes the GWPS when this value is greater than the MCL or if an MCL does not exist for the constituent. However, if most background data are non-detect, then detected concentrations are likely less than the MCL (if the MCL exists), and the GWPS will be set at the MCL.

If recent data are mostly non-detect, non-parametric confidence intervals can be constructed around the median by ranking the data from least to greatest and setting the LCL equal to one of the lower values of data. The confidence can be calculated based on the rank of the data point used and the sample size. Confidence values are tabulated in Table 21-11 in Appendix D of the Unified Guidance for sample sizes up to 20 (USEPA, 2009).

However, if most of the recent data are non-detect, then the data point selected for the LCL will also be non-detect. If the RL is less than the GWPS, then no statistically significant exceedance has occurred.

GWPSs should only be determined for detected Appendix IV constituents [30 TAC 352.951(b)]. If all the data for a constituent are non-detect, no statistical evaluation need be performed.

4.1.2 Data Are neither Normal nor Transformed-Normal

If background data are non-normal and cannot be transformed such that the transformed data do follow a normal distribution, then non-parametric tolerance intervals should be used. In these cases, the UTL is set at either the highest or second-highest concentration observed in the background dataset.

If recent data are non-normal and cannot be transformed such that the transformed data do follow a normal distribution, non-parametric confidence intervals can be constructed around the median by ranking the data from least to greatest and setting the LCL equal to one of the lower values of data. The confidence can be calculated based on the rank of the data point used and the sample size. Confidence values are tabulated in Table 21-11 in Appendix D of the Unified Guidance for sample sizes up to 20 (USEPA, 2009).

4.1.3 A Significant Temporal Trend Exists

If recent data show a significant temporal trend, then an LCL below the trend line can be calculated according to the following equation:

$$\mathrm{LCL} = \widehat{x_0} - \sqrt{2s_e^2 * F_{1-2\alpha,2,n-2} * \left(\frac{1}{n} + \frac{(t_0 - \bar{t})^2}{(n-1)s_t^2}\right)} \quad (9)$$

where:

$\widehat{x_0} =$ regression-line estimate of the mean concentration at time t_0
$s_e =$ standard error of the regression line
$F_{1-2\alpha,2,n-2} =$ upper (1 - 2α)th percentage point from an F-distribution with 2 and n – 2 degrees of freedom
$n =$ number of samples in the recent dataset
$t_0 =$ date of the most recent groundwater sample
$\bar{t} =$ mean of the sampling dates in the recent dataset
$s_t =$ standard deviation of the sampling dates in the recent dataset

Note that the LCL is a function of time; to assess current compliance, the date of the most recent sample should be used for t_0. If and only if the LCL is greater than the GWPS at this time, then a statistically significant exceedance can be concluded. This equation can also be used to assess when the LCL will exceed the GWPS (assuming the current trend continues).

The same α that would have been selected if there were no significant trend (as described in **Section 4.1**) should be used here to determine the proper F value.

If the Theil-Sen method is used to determine the trend line, a computationally intensive technique known as bootstrapping can be used to determine the LCL. This procedure is described in Section 21.3.2 of the Unified Guidance (USEPA, 2009).

4.1.4 A Significant Seasonal Pattern Exists

If a statistically significant seasonal pattern exists in the background data and if there is a physical explanation for the seasonality, the background data should be deseasonalized using the procedure described in **Section 2.6**. The background-based UTL should be calculated based on the deseasonalized data, and the GWPS should be set at the MCL or (if an MCL does not exist for that constituent or if background data are higher than the MCL) the background-based UTL, whichever is greater.

Similarly, if a statistically significant seasonal pattern exists in compliance well data and if there is a physical explanation for the seasonality, the compliance well data should be deseasonalized using the procedure described in **Section 2.6**. The LCL to be compared to the GWPS should be calculated based on the deseasonalized compliance well data.

4.2 Comparing Data to Background

Assessment monitoring data must be compared to the GWPS to assess whether corrective action is warranted at the CCR unit (i.e. the LCL exceeds the GWPS). Additionally, assessment monitoring data may be compared to background data to assess whether the CCR unit can move from assessment monitoring back to detection monitoring.

To return from assessment monitoring to detection monitoring, the CCR rules specify that all Appendix III and IV constituents must be at or below background levels for two consecutive sampling events and written approval needs to be received from TCEQ [30 TAC 352.951(c)]. However, the analysis of all Appendix III and IV constituents is not required for every monitoring event. Therefore, all Appendix III and IV constituents should be collected during two consecutive sampling events on a periodic basis (e.g., every two to four years) and/or when statistical evaluation of assessment monitoring data suggests groundwater concentrations are at or below background levels.

A UTL can be used to represent “a reasonable maximum on likely background concentrations” for Appendix III and IV constituents (USEPA, 2009). As described previously, UTLs can be determined parametrically or non-parametrically. For the parametric intervals, the UTL is calculated according to Equation 7. Non-parametric UTLs can be determined by setting the UTL to the highest or second-highest measured background value. If all background data are non-detect, then non-detect results in compliance wells can be considered statistically similar to background. If a temporal trend in background data exists and is not attributable to a release, background data can be truncated so that no significant temporal trend is evident.

To determine whether Appendix III and IV constituents are at or below background levels, a confidence interval constructed on recent data at each compliance monitoring well should be compared to the background UTL for each constituent. When the upper confidence limit (UCL) is below the background UTL, then it can be concluded that concentrations are at or below background. If UCLs are less than background UTLs for every constituent at every monitoring well for two consecutive events, then the CCR unit may return to detection monitoring.

When most of the data are detections, data are normally distributed, and there is no significant temporal trend, the UCL is calculated according to the following equation:

$$\mathrm{UCL} = \bar{x} + t_{1-\alpha,n-1} * \frac{s}{\sqrt{n}} \quad (10)$$

where:

$\bar{x} =$ mean concentration of the recent dataset
$t_{1-\alpha,n-1} =$ one-tailed *t*-value at a confidence of 1 – α and at n – 1 degrees of freedom
$s =$ standard deviation of the recent dataset
$n =$ number of samples in the recent dataset

If recent data are mostly non-detect or are non-normal and cannot be transformed such that the transformed data follow a normal distribution, non-parametric confidence intervals can be constructed around the median by ranking the data from least to greatest and setting the UCL equal to one of the higher values of data. The confidence can be calculated based on the rank of the data point used and the sample size. Confidence values are tabulated in Table 21-11 in Appendix D of the Unified Guidance for sample sizes up to 20 (USEPA, 2009).

If recent data show a significant temporal trend, then a UCL above the trend line can be calculated according to the following equation:

$$\mathrm{UCL} = \widehat{x_0} + \sqrt{2s_e^2 * F_{1-2\alpha,2,n-2} * \left(\frac{1}{n} + \frac{(t_0 - \bar{t})^2}{(n-1)s_t^2}\right)} \quad (11)$$

where:

$\widehat{x_0} =$ regression-line estimate of the mean concentration at time t_0
$s_e =$ standard error of the regression line
$F_{1-2\alpha,2,n-2} =$ upper (1 - 2α)th percentage point from an F-distribution with 2 and n – 2 degrees of freedom
$n =$ number of samples in the recent dataset
$t_0 =$ date of the most recent groundwater sample
$\bar{t} =$ mean of the sampling dates in the recent dataset
$s_t =$ standard deviation of the sampling dates in the recent dataset

In all cases, the choice of τ and α (for parametric UTLs and UCLs, respectively), the choice of the highest or second-highest data point (for non-parametric UTLs and UCLs), etc. should be made based on sound statistical judgment and site characteristics (e.g., size of datasets, number of monitoring wells, etc.).

4.3 Required Responses to the Results of the Statistical Evaluation

If the statistical evaluation demonstrates that the concentrations of all Appendix III and Appendix IV constituents are at or below background levels for two consecutive sampling events, then the CCR unit may return to detection monitoring with written approval from TCEQ [30 TAC 352.951(c)]. A notification that the CCR unit is returning to detection monitoring must be placed in the facility's operating record.

If the statistical evaluation demonstrates that some Appendix III or Appendix IV constituents are at concentrations above background levels but there are no statistically significant exceedances of GWPSs, then the CCR unit must remain in assessment monitoring [30 TAC 352.951(a)].

If the statistical evaluation demonstrates that an Appendix IV constituent is present at a statistically significant level (SSL) above its GWPS (i.e., if the LCL exceeds the GWPS), then the owner/operator must:

- Provide a written notification to TCEQ and any local pollution agencies with jurisdiction that had requested to be notified within 14 days of the determination [30 TAC 352.951(d)];

- Include a notification in the facility's operating record that identifies the constituents exceeding GWPSs [30 TAC 352.951(a)];

- Characterize the nature and extent of the release, including installing monitoring wells needed to delineate the plume, installing a monitoring well at the downgradient property boundary, quantifying the nature and the amount of the release, and sampling all wells for Appendix III and detected Appendix IV constituents [30 TAC 352.951(a)];

- If the plume has migrated off-site, notify property owners overlying the plume [30 TAC 352.951(a)]; and

- Either begin an assessment of corrective measures or demonstrate that the SSL is not due to a release from the CCR unit within 90 days of completing the statistical evaluation [30 TAC 352.951(e)]. This demonstration must be made in writing, certified by a qualified professional engineer, and submitted to TCEQ and any local pollution agency with jurisdiction that had requested to be notified [30 TAC 352.951(e)]. The CCR rules require the previous four actions to be taken even if it can be demonstrated that the SSL is not due to a release from the CCR unit.

Reporting requirements for assessment monitoring are summarized in **Section 6.2**.

4.4 Updating Background

Care should be taken when updating background during assessment monitoring since, by definition, an SSI over background has already occurred. Data that appear to be affected by a release from the CCR unit should not be included in updated background datasets. However, it may be possible to update some background datasets (e.g., constituents not associated with a release, wells upgradient of the CCR unit, etc.). Formal updating of Appendix III and Appendix IV constituents may be considered when there are at least four new points.

Data should be reviewed every four to eight measurements to assess the possibility of updating background datasets. Professional judgment should first be applied; any data that appear to be affected by a release should be excluded from the background update, even if there is no statistically significant difference between the new data and the existing background data.

For data that appear not to be affected by a release, a Student's *t*-test or Mann-Whitney test should be conducted to compare the set of new data points against the existing background dataset. If the *t*-test or Mann-Whitney test corroborates that there are no significant differences, the new data should be combined with the existing background data to create an updated and expanded background dataset. Increasing the size of the background dataset will increase the power of subsequent statistical tests.

If the *t*-test or Mann-Whitney test indicates a statistically significant difference between the two datasets, then it should be considered that the difference results from a release and the existing background dataset should continue to be used. If and only if there is evidence to suggest that the difference is not related to a release from the CCR unit, then the newer set of measurements should be used for background so that resulting statistical limits are representative of present-day groundwater quality conditions.

Periodically, spatial variability among background wells may be re-assessed to determine whether using an interwell or intrawell comparison is appropriate on a constituent-by-constituent basis, as outlined in **Section 3.1**.

SECTION 5

CORRECTIVE ACTION MONITORING

A CCR unit must begin an assessment of corrective measures if an SSL is identified and is not attributed to some cause other than a release from the CCR unit. The assessment of corrective measures must begin within 90 days of identifying the SSL [30 TAC 352.951(f)]. Based on the results of the corrective measures assessment, a remedy must be selected as soon as feasible [30 TAC 352.971(a)]. A schedule for implementing and completing the remedial activities must be included in the remedy selection [30 TAC 352.971(a)]. The owner/operator must begin remedial activities within 90 days of selecting a remedy, and a corrective action groundwater monitoring program must be implemented based on the schedule established as part of the remedy selection [30 TAC 352.981(a)].

The corrective action monitoring program must [30 TAC 352.981(a)]:

- Meet the requirements of an assessment monitoring program;
- Document the effectiveness of the remedy; and
- Demonstrate compliance with the GWPS.

The statistical methods used in corrective action monitoring are similar to those used in assessment monitoring. For each detected Appendix IV constituent, a GWPS is set at the MCL or (if an MCL does not exist for that constituent or if background data are higher than the MCL) a value based on background data, whichever is greater. A confidence interval is constructed based on recent data at each compliance well, and the confidence interval is compared to the site-wide GWPS. However, in assessment monitoring, the presumption is that a release has not occurred, and a release is concluded when average concentrations are higher than the GWPS (i.e., when the *lower* confidence limit [LCL] is *greater* than the GWPS). If a CCR unit is in corrective action monitoring, then evidence of a release has already been identified. Therefore, in corrective action monitoring, the presumption is that a release has occurred, and the conclusion that the remedy has successfully decreased concentrations below the GWPS is made when average concentrations are less than the GWPS (i.e., when the *upper* confidence limit [UCL] is *less* than the GWPS). (Note that this presumption only applies to well-constituent pairs where an SSL has previously been identified. Well-constituent pairs in assessment monitoring where an SSL has not been identified effectively remain in assessment monitoring until the entire unit returns to detection monitoring.)

A remedy is considered complete when, among other things, confidence intervals constructed for Appendix IV constituents for wells identified with SSLs have not exceeded the GWPS for three consecutive years [30 TAC 352.981(a)]. In this instance, a return to assessment monitoring would be warranted.

Upon completion of the remedy, the owner/operator must prepare a notification stating that the remedy is complete. The notification must be certified by a qualified professional engineer and submitted to TCEQ for approval before placement in the operating record [30 TAC 352.981(a)].

Prior to returning to assessment monitoring, documentation must be submitted to TCEQ that includes:

- Analytical data prepared and presented in accordance with 30 TAC 352.931 [30 TAC 352.981(b)(1)];
- A narrative discussing how the requirements of this section have been fulfilled for the impacted property [30 TAC 352.981(b)(2)]; and
- A description of the volume and final disposal location, and copies of waste manifests or documentation of disposal for waste or environmental media that had been removed from the impacted property [30 TAC 352.981(b)(3)].

The return to assessment monitoring must be approved by TCEQ in writing.

Otherwise, the owner/operator should follow the reporting requirements for assessment monitoring, as summarized in **Section 6.2**.

5.1 Comparing Data to the GWPS

As stated in **Section 5**, the GWPS is set at the MCL or (if an MCL does not exist for that constituent or if background data are higher than the MCL) a value based on background data, whichever is greater. The UTL calculated from the background dataset is often used as the background value. The UTL is calculated as described in **Section 4.1**. Methods for updating background are described in **Section 4.4**.

For well-constituent pairs in corrective action monitoring, new data must be evaluated to determine whether they are statistically significantly lower than the GWPS. The statistical analyses listed in 40 CFR 257.93(f), as included by reference in 30 TAC 352.931(a) are appropriate for comparing new data to a background dataset but are not appropriate for comparing new data to a fixed standard. For these cases, the Unified Guidance recommends using confidence intervals around the mean or median (USEPA, 2009).

When selecting which data to include in the recent dataset, time series plots of concentration data at each well should be created and visually inspected. Only data that exhibit the same behavior as recent data should be included. For instance, if the last eight arsenic results cluster around 9 µg/L and the previous eight results cluster around 4 µg/L, then only the eight most recent results should be used in the statistical analysis. Similarly, if chromium concentrations steadily increased over the last ten samples and were stable previously, then the statistical analysis should only use the ten most recent results and (since they are steadily increasing) should involve constructing a confidence interval around a trend line.

At the same time, datasets should also be sufficiently large to maintain statistical power. As many data points that exhibit the same behavior as recent data as possible should be included, including data collected prior to assessment monitoring (e.g., during the initial eight monitoring events). Ideally, datasets should have at least eight data points; in no case should a dataset have fewer than four data points.

If at least 50% of the recent dataset is non-detect, then a parametric confidence interval should not be used, and the procedure in **Section 5.1.1** should be followed.

New data will be evaluated for statistically significant temporal trends using (1) OLS linear regression with a *t*-test ($\alpha = 0.01$) on the slope and/or (2) the non-parametric Theil-Sen slope estimator with Mann-Kendall trend test ($\alpha = 0.05$, or 0.01 for larger datasets). Non-detect data are replaced with half the RL for these analyses. The OLS linear regression or Theil-Sen slope estimator will be used to estimate the rate of change (increasing, no change, or decreasing) over time for each constituent at each well. The *t*-test or Mann-Kendall statistic will be used to determine whether a trend is statistically significant. OLS linear regression should only be used when at most 15% of the data are non-detect, when regression residuals are normally distributed, and when the variance from the regression line does not change over time. The Theil-Sen/Mann-Kendall analysis requires at least five observations for meaningful results; at least eight observations are recommended. If a significant temporal trend exists, then a confidence interval around the trend line should be constructed as outlined in **Section 5.1.3**.

If the trend analysis does not indicate a statistically significant trend, then the mean and variance should be calculated. If fewer than 15% of the data are non-detect, then the non-detect data can be replaced with half the RL and the mean and variance can be calculated normally. Tolerance intervals are sensitive to the choice of population distribution. Normality should be confirmed using the Shapiro-Wilk (or Shapiro-Francía) test and/or probability plots, as described in **Section 2.2**. If data appear not to be normally distributed, data should be transformed so that the transformed data are normally distributed.

Two methods – the Kaplan-Meier or Robust ROS method – can be used to determine the sample mean and variance when 15% to 50% of the data are non-detect. Kaplan-Meier should not be used if all non-detect data have the same RL or if the maximum detected value is less than the highest RL of the non-detect data.

When most of the data are detections, data are normally distributed, and there is no significant temporal trend, the UCL is calculated according to the following equation:

$$\mathrm{UCL} = \bar{x} + t_{1-\alpha,n-1} * \frac{s}{\sqrt{n}} \quad (10)$$

where:

$\bar{x} =$ mean concentration of the recent dataset
$t_{1-\alpha,n-1} =$ one-tailed *t*-value at a confidence of 1 – α and at n – 1 degrees of freedom
$s =$ standard deviation of the recent dataset
$n =$ number of samples in the recent dataset

The *t* value must be chosen in such a way to balance the competing goals of a low false-positive rate and a high statistical power. The Unified Guidance recommends that the statistical test have at least 80% power ($1 - \beta = 0.8$) when the underlying mean concentration is twice the MCL (USEPA, 2009). Values of the minimum α (from which *t* values can be determined) are tabulated for this criterion for various values of *n* in Table 22-2 in Appendix D of the Unified Guidance (USEPA, 2009). The selected α should be the maximum of the value in Table 22-2 and 0.01.

If data are transformed normal, the UCL should first be calculated for the transformed data and then be transformed back into concentration terms. Correction factors are available but are not expected to be required. Alternatively, a non-parametric UCL can be used, as described in **Section 5.1.2**.

If data are non-normal and cannot be transformed such that the transformed data do follow a normal distribution, then a non-parametric UCL should be used, as described in **Section 5.1.2**.

5.1.1 Most Data Are Non-Detect

If recent data are mostly non-detect, non-parametric confidence intervals can be constructed around the median by ranking the data from least to greatest and setting the UCL equal to one of the higher values of data. The confidence can be calculated based on the rank of the data point used and the sample size. Confidence values are tabulated in Table 21-11 in Appendix D of the Unified Guidance for sample sizes up to 20 (USEPA, 2009).

5.1.2 Data Are neither Normal nor Transformed-Normal

If recent data are non-normal and cannot be transformed such that the transformed data do follow a normal distribution, non-parametric confidence intervals can be constructed around the median by ranking the data from least to greatest and setting the UCL equal to one of the higher values of data. The confidence can be calculated based on the rank of the data point used and the sample size. Confidence values are tabulated in Table 21-11 in Appendix D of the Unified Guidance for sample sizes up to 20 (USEPA, 2009).

5.1.3 A Significant Temporal Trend Exists

If recent data show a significant temporal trend, then a UCL above the trend line can be calculated according to the following equation:

$$\mathrm{UCL} = \widehat{x_0} + \sqrt{2s_e^2 * F_{1-2\alpha,2,n-2} * \left(\frac{1}{n} + \frac{(t_0 - \bar{t})^2}{(n-1)s_t^2}\right)} \quad (11)$$

where:

$\widehat{x_0} =$ regression-line estimate of the mean concentration at time t_0
$s_e =$ standard error of the regression line
$F_{1-2\alpha,2,n-2} =$ upper (1 - 2α)th percentage point from an F-distribution with 2 and n – 2 degrees of freedom
$n =$ number of samples in the recent dataset
$t_0 =$ date of the most recent groundwater sample
$\bar{t} =$ mean of the sampling dates in the recent dataset
$s_t =$ standard deviation of the sampling dates in the recent dataset

Note that the UCL is a function of time; to assess current compliance, the date of the most recent sample should be used for t_0. If and only if the UCL is less than the GWPS at this time, then it can be concluded that the remedy has successfully decreased concentrations below the GWPS. This equation can also be used to assess when the UCL will decrease below the GWPS (assuming the current trend continues).

The same α that would have been selected if there were no significant trend (as described in **Section 5.1**) should be used here to determine the proper *F* value.

If the Theil-Sen method is used to determine the trend line, a computationally intensive technique known as bootstrapping can be used to determine the UCL. This procedure is described in Section 21.3.2 of the Unified Guidance (USEPA, 2009).

5.1.4 A Significant Seasonal Pattern Exists

If a statistically significant seasonal pattern exists in compliance well data and if there is a physical explanation for the seasonality, the compliance well data should be deseasonalized using the procedure described in **Section 2.6**. The UCL to be compared to the GWPS should be calculated based on the deseasonalized compliance well data.

SECTION 6

REPORTING REQUIREMENTS

The CCR rule specifies reporting requirements throughout the monitoring process. Throughout the process, the required documentation is required to be posted both to the site's operating record and to a public internet set for review. As required by 30 TAC 352.931(a), the chosen statistical methods described within this SAP are certified by a qualified professional engineer as appropriate for groundwater evaluation (**Section 7**).

6.1 Annual Groundwater Monitoring and Corrective Action Report

By January 31 of each year, all existing facilities must submit an Annual Groundwater Monitoring and Corrective Action Report (Annual Report) [30 TAC 352.901(a)]. The Annual Report should be prepared and posted to both the site operating record and the public internet site. The Annual Report must also be submitted to TCEQ for approval no later than 30 days after the report has been placed on the facility's operating record [30 TAC 352.902].

The Annual Report should document site status, summarize key actions taken, describe problems encountered and their resolutions, and project key actions to be taken for the following year. The Annual Report should also include [30 TAC 352.901(a)]:

- A figure showing the CCR unit and the monitoring well network;
- An identification of monitoring wells installed or abandoned during the preceding year and the rationale for doing so;
- A summary of groundwater samples collected, which wells were sampled, what dates the samples were collected, and whether the samples were collected for detection monitoring or assessment monitoring; and
- A discussion of any transition between monitoring programs (i.e., detection monitoring vs. assessment monitoring vs. corrective action monitoring.

If appropriate, the Annual Report should detail a demonstration for an alternative groundwater sampling frequency. If no SSIs are identified during each sampling event, an updated Annual Report should be submitted yearly.

6.2 Detection Monitoring

If SSIs are identified, TCEQ and any local pollution agencies with jurisdiction that had requested to be notified should be notified in writing within 14 days of the SSI determination [30 TAC 352.941(b)] and intention to make an alternative source demonstration [30 TAC 352.941(c)(1)]. The facility should demonstrate within 90 days of the detection, where possible, that SSIs over background are not due to a release from the facility, along with a certification by a qualified professional engineer that the information is accurate. The report documenting this demonstration must be submitted to TCEQ for approval and to any local pollution agencies with jurisdiction that had requested to be notified [30 TAC 352.941(c)(2)]. Additionally, the report should be included in the Annual Report. If the SSIs over background are attributed to a release from the facility, the facility should prepare and place in the operating record within 90 days a notification stating that an assessment monitoring program has been established [30 TAC 352.941(a)]. Additionally, the assessment monitoring program must be approved by TCEQ [30 TAC 352.941(d)].

6.3 Assessment Monitoring

If an assessment monitoring program is in place, the Annual Report must also include [30 TAC 352.951(a)]:

- Analytical results for Appendix III and detected Appendix IV constituents,
- Background concentrations for all Appendix III and Appendix IV constituents, and
- GWPSs established for detected Appendix IV constituents.

The semiannual analytical results for Appendix III and detected Appendix IV constituents must also be posted to the facility's operating record within 90 days of receipt [30 TAC 352.951(a)]. If a constituent is detected at an SSL above its GWPS, a notification must be reported to the site's operating record [30 TAC 352.951(a)]. The owner or operator must also submit a written notification to TCEQ and any local pollution agencies with jurisdiction that had requested to be notified within 14 days identifying the SSLs and specifying a plan and schedule for analyzing the release and for developing appropriate corrective action [30 TAC 352.951(d)].

Additionally, the facility must notify any person who owns or resides on land that directly overlies any part of an off-site contaminant plume and record the notifications in the facility's operating record. Within 90 days, the facility must either initiate an assessment of corrective measures or demonstrate that the SSL is not due to a release from the CCR unit. The demonstration must be supported by a report certified by a qualified professional engineer and submitted to TCEQ for approval [30 TAC 352.951(e)].

If the facility determines it may return to detection monitoring and received approval from TCEQ, the facility should issue a notification to the operating record and public site within 30 days [30 TAC 352.1301(a)].

6.4 Corrective Action Monitoring

If a corrective action monitoring program is in place, it must meet the requirements of an assessment monitoring program [30 TAC 352.981(a)]. Thus, the reporting requirements for corrective action monitoring will be similar to assessment monitoring, as described in **Section 6.3**. Upon completion of the remedy, the facility must prepare a notification that the remedy has been completed [30 TAC 352.981(b)]. The notification must be certified by a qualified professional engineer, approved by TCEQ, and placed in the operating record [30 TAC 352.981(a) and 30 TAC 352.981(c)].

SECTION 7

CERTIFICATION BY QUALIFIED PROFESSIONAL ENGINEER

By means of this certification, I certify that I am a qualified professional engineer as defined in 30 TAC 352.3(a), that I have reviewed this SAP, and that the statistical methods described therein are appropriate and meet the requirements of 30 TAC 352.931.

	Selenium
	Thallium

ATTACHMENT A

Record of Revisions

ATTACHMENT A

RECORD OF REVISIONS

Revision 1 (October 2020)

- Added statistical procedures used to implement corrective action monitoring (Section 5) and reporting requirements for corrective action monitoring (Section 6.5).
- Added references to CCR rule-specified screening levels for constituents that do not have an MCL (i.e., cobalt, lead, lithium, and molybdenum) in Sections 2.5, 4, 4.1, and 5.1.
- Added statistical procedures used to evaluate whether a seasonal pattern exists and to deseasonalize data (Sections 2.6, 3.2.5, 4.1.4, and 5.1.4).
- Specified that the Mann-Kendall trend test can use an α of 0.01 for sufficiently large datasets (Sections 3.1, 4.1, and 5.1).
- Removed references to control limits in Section 3.2 because prediction limits are generally being used to conduct detection monitoring.
- Removed references to using trend tests to evaluate SSIs at the end of Section 3.2 because prediction limits are generally being used to conduct detection monitoring.
- Clarified that non-parametric limits should be used when data are non-normal and cannot be transformed such that the transformed data do follow a normal distribution (Sections 3.2.3, 4.1.2, and 5.1.2).
- Referred to the Wilcoxon rank-sum/Mann-Whitney test as the Mann-Whitney test to match the statistical output from Sanitas (Sections 3.4 and 4.4).
- Clarified that a background dataset that contains at least five data points is sufficiently large to use an α as low as 0.01 to conduct the Mann-Whitney test as part of a background update, in line with recommendations in the Unified Guidance (Section 3.4).
- Clarified the procedure to be used if the Mann-Whitney test indicates a statistically significant difference between existing background data and newer data (Sections 3.4 and 4.4).
- Clarified that spatial variability among background wells may be assessed periodically as part of a background update because spatial variability is evaluated when background values are initially established (Sections 3.4 and 4.4).

- Added statistical procedures to determine when Appendix III and Appendix IV concentrations are at or below background to evaluate whether units in assessment monitoring may return to detection monitoring (Section 4.2).

- Generally replaced “parameter” with “constituent”.

- Added references to the Unified Guidance and the CCR rule throughout the document.

- Made minor grammatical and stylistic changes throughout the document.

Revision 2 (November 2021)

- Removed references to screening levels for constituents that do not have an MCL.

- Updated references from the Code of Federal Regulations to Texas Administrative Code.

4.7 – Statistical Analysis Summary, Landfill, H.W. Pirkey Power Plant, Hallsville, Texas, January 3, 2018

Purpose of Statistical Analysis Summary Report

During the initial phase of ground water monitoring, the CCR rule requires AEP to collect at least eight independent samples from at least one up-gradient and three downgradient wells for 21 substances listed in the CCR rule. The CCR rule also requires us to select a statistical method that will be used to evaluate the samples in the later phases of the ground water monitoring program. The Statistical Plan, which has been posted to AEP's CCR website, describes the methods selected by AEP. *See* AEP's Statistical Analysis Plans.

Each **Statistical Analysis Summary Report** is based on the results of the 8 independent samples that were collected by October 17, 2017, and reported in the Annual Groundwater Monitoring Report. Using the statistical methods chosen by AEP, the samples were evaluated to eliminate outliers, determine variability and general trends in the data, and establish background values for: boron, calcium chloride, fluoride, pH, sulfate, and total dissolved solids. Appendix IV substances were evaluated for purposes of identifying outliers and understanding data trends.

A subsequent sample taken during the first detection monitoring sampling event was also compared using the proper statistical methods to the background values that were established for these seven substances from the eight independent samples. A second or third re-sampling event occurred, and the results compared using the same methods. This work is reported in the memorandum included in attachment A. If confirmed, AEP will be required to enter the next phase of monitoring. The results of future sampling will be further analyzed to target any specific substances for which ongoing monitoring or potential corrective action is required.

SECTION 1

EXECUTIVE SUMMARY

In accordance with the United States Environmental Protection Agency's (USEPA's) regulations regarding the disposal of coal combustion residuals (CCR) in landfills and surface impoundments (40 CFR 257.90-257.98, "CCR rule"), groundwater monitoring has been conducted at the landfill, an existing CCR unit at the H.W. Pirkey Power Plant located in Hallsville, Texas.

Eight monitoring events were completed prior to October 17, 2017 to establish background concentrations for Appendix III and Appendix IV parameters under the CCR rule. Groundwater data underwent several validation tests, including those for completeness, sample tracking accuracy, transcription errors, and consistent use of measurement units. No data quality issues were identified which would impact the usability of the data.

The monitoring data were submitted to Groundwater Stats Consulting, LLC for statistical analysis. The background data were reviewed for outliers, which were removed (when appropriate) prior to calculating upper prediction limits (UPLs) for each Appendix III parameter to represent background values. Oversight on the use of statistical calculations was provided by Dr. Kirk Cameron of MacStat Consulting, Ltd.

A groundwater sampling event occurred on August 23 and 24, 2017 at the landfill. This sampling event obtained the first sample for the 1-of-2 prediction interval statistical test used for detection monitoring. The results of this sampling event are included in this report.

SECTION 2

LANDFILL EVALUATION

2.1 Data Validation & QA/QC

During the background monitoring program, eight sets of samples were collected for analysis from each upgradient and downgradient well. A summary of data collected during background and detection monitoring sampling may be found in Table 1.

Chemical analysis was completed by an analytical laboratory certified by the National Environmental Laboratory Accreditation Program (NELAP). Quality assurance and quality control (QA/QC) samples completed by the analytical laboratory included the use of laboratory reagent blanks (LRBs), continuing calibration verification (CCV) samples, and laboratory fortified blanks (LFBs).

The analytical data were imported into a Microsoft Access database, where checks were completed to assess the accuracy of sample location identification and analyte identification. Where necessary, unit conversions were applied to standardize reported units across all sampling events. Exported data files were created for use with the Sanitas™ v.9.5.32 statistics software. The export was checked against the analytical data for transcription errors and completeness. No QA/QC issues were noted which would impact data usability.

2.2 Statistical Analysis

The background data used to conduct the statistical analyses are summarized in Table 1. Statistical analyses for the landfill were conducted in accordance with the January 2017 *Statistical Analysis Plan* (AEP, 2017), except where noted below. Results for all completed statistical tests are provided in Attachment A.

Time series plots of Appendix III and IV parameters are included in Attachment A. Mann-Kendall analyses ($\alpha = 0.01$) were conducted to evaluate trends in the background data. Mercury was found to be significantly decreasing at downgradient well AD-34. No other significant increasing or decreasing trends were observed for other parameters or at other monitoring wells.

2.2.1 Background Outlier Evaluation

Potential outliers were identified using Tukey's outlier test; i.e., data points were considered potential outliers if they met one of the following criteria:

$$x_i < \tilde{x}_{0.25} - 3 \times IQR \quad (1)$$

or

$$x_i > \tilde{x}_{0.75} + 3 \times IQR \quad (2)$$

where:

$x_i =$ individual data point
$\tilde{x}_{0.25} =$ first quartile
$\tilde{x}_{0.75} =$ third quartile
$IQR =$ the interquartile range $= \tilde{x}_{0.75} - \tilde{x}_{0.25}$

Data that were evaluated as potential outliers are summarized in Attachment A. Tukey's outlier test indicated 17 potential outliers, which are summarized in Table 2. Next, the data were reviewed to identify possible sources of errors or discrepancies, including data recording errors, unusual sampling conditions, laboratory quality indicators, or inconsistent sample turbidity. The findings of this data review are summarized below.

The primary sample result for fluoride collected on October 12, 2016 at upgradient well AD-12 (4.717 mg/L) was replaced with the duplicate sample result. Fluoride was not detected in the duplicate sample at a reporting limit of 1.0 mg/L. The duplicate sample was considered more representative based on the reported concentrations from the other background sampling events. The reported fluoride concentration of 0.2565 mg/L at AD-12 on April 11, 2017 was also identified as an outlier. However, it was an estimated (J-flagged) value and was not removed from the database.

Thirteen of the potential outliers were associated with mercury in upgradient wells. Several of the mercury samples were not detected and were reported as the reporting limit. Thus, samples which did have detectable concentrations of mercury were often identified as high potential outliers. These values were retained in the database, as they are likely reflective of aquifer conditions. Likewise, several estimated (J-flagged) mercury concentrations were identified as potential low outliers and were retained in the database.

The reported lithium concentration of 0.0001358 mg/L at AD-23 on May 10, 2016 was an estimated (J-flagged) value and was retained within the dataset. The reported lithium concentration of 1.01 mg/L at AD-23 on October 12, 2016 was also identified as a potential outlier. The sample was removed from the dataset because high turbidity was reported during sample collection, suggesting possible sampling error. The removed lithium value was associated with a downgradient monitoring well; therefore, its removal did not affect the calculation of background levels presented below.

2.2.2 Establishment of Background Levels

Analysis of variance (ANOVA) was conducted to determine whether spatial variation was present among the four upgradient wells (Attachment A). ANOVA indicated no significant variation among the four upgradient wells for pH. Consequently, interwell tests were used for pH. Significant variation was observed for boron, calcium, chloride, fluoride, sulfate, and total dissolved solids (TDS). Therefore, the appropriateness of using intrawell tests was evaluated for all Appendix III parameters at the Pirkey Plant Landfill.

Intrawell tests presume that the groundwater quality in the downgradient wells was not initially impacted by the CCR unit. To test this presumption, the data from the upgradient wells were pooled and the data from each downgradient well were compared to a pooled background value. Tolerance limits were calculated using the pooled background data for boron, calcium, chloride, fluoride, sulfate, and TDS. Parametric tolerance limits with 99% confidence and 95% coverage were calculated for calcium, chloride, and TDS. Non-parametric tolerance limits were calculated for boron, fluoride, and sulfate, due to non-normality, high frequency (more than 50%) of non-detects, and especially high observed spatial variability, respectively. Confidence intervals were calculated for each of these six parameters for each downgradient monitoring well. If the lower confidence limit from a downgradient well exceeded the upper tolerance limit for the pooled background data, it was concluded that downgradient groundwater concentrations were above background concentrations. In these instances, intrawell tests would not be appropriate. However, these analyses indicated no significant exceedances for boron, calcium, chloride, and fluoride; elevated concentrations of sulfate and TDS were observed. (Non-parametric analyses also indicated elevated TDS concentrations in downgradient wells and no significant exceedances for calcium. A non-parametric analysis for chloride indicated elevated chloride concentrations at downgradient well AD-35.) Therefore, intrawell tests were used to evaluate potential SSIs for boron, calcium, chloride, and fluoride. Parametric interwell tests were used to evaluate potential SSIs for pH, sulfate, and TDS.

After equality of variance was tested and identified outliers were removed (where appropriate), a parametric or non-parametric analysis was selected based on the distribution of the data and the frequency of non-detect data. Estimated results less than the practical quantitation limit (PQL) – i.e., “J-flagged” data – were considered detections and the estimated results were used in the statistical analyses. Non-parametric analyses were selected for datasets with at least 50% non-detect data or datasets that could not be normalized. Parametric analyses were selected for datasets (either transformed or untransformed) that passed the Shapiro-Wilk / Shapiro-Francía test for normality. The Kaplan-Meier non-detect adjustment was applied to datasets with between 15% and 50% non-detect data. For datasets with fewer than 15% non-detect data, non-detect data were replaced with one half of the PQL. The selected analysis (i.e., parametric or non-parametric) and transformation (where applicable) for each background dataset are shown in Attachment A.

Upper prediction limits (UPLs) were calculated for each Appendix III parameter to represent background values. A lower prediction limit (LPL) was also calculated for pH. To conduct the intrawell tests for boron, calcium, chloride, and fluoride, a separate UPL was calculated for each downgradient well for each of these parameters. To conduct the interwell tests for pH, sulfate, and TDS, a single prediction interval was calculated for each of these parameters using pooled data from the four upgradient wells. The background data used for the UPL calculations are summarized in Table 1; the calculated UPLs are summarized in Table 3.

UPLs were calculated for a one-of-two retesting procedure; i.e., if at least one sample in a series of two does not exceed the UPL, then it can be concluded that an SSI has not occurred. In practice, where initial results did not exceed the UPL, a second sample was not collected. The one-of-two retesting procedure allowed achieving an acceptably high statistical power while maintaining a site-wide false-positive rate (SWFPR) of 10% per year or less. Power curves were constructed for the interwell and intrawell parametric tests and are compared with the EPA Reference Power Curve in Appendix A. The power curves associated with the statistical tests for the Pirkey Plant Landfill exceed the EPA Reference Power Curve at 3 and 4 standard deviations; this is considered a "good" level of statistical power according to EPA's *Unified Guidance* (USEPA, 2009).

2.2.3 Certification by Qualified Professional Engineer

I certify that the selected and above described statistical method is appropriate for evaluating the groundwater monitoring data for the Pirkey Landfill CCR management area and that the requirements of 40 CFR 257.93(f) have been met.

2.3 Conclusions

Eight background monitoring and one detection monitoring event were completed in accordance with the CCR Rule. The laboratory and field data were reviewed prior to statistical analysis, with no QA/QC issues identified that impacted data usability. A review of outliers identified seventeen potential outliers, with one value removed from the dataset without replacement. Prediction intervals were constructed based on the remaining background data and a one-of-two retesting procedure. Interwell tests were selected for pH, sulfate, and TDS, whereas intrawell tests were selected for boron, calcium, chloride, and fluoride.

Memorandum

Date:	February 27, 2018
To:	David Miller (AEP)
Copies to:	Terence Wehling (AEP)
From:	Allison Kreinberg and Bruce Sass, Ph.D. (Geosyntec)
Subject:	Evaluation of Detection Monitoring Data at H.W. Pirkey Plant's Landfill (LF)

In accordance with the United States Environmental Protection Agency's (USEPA's) regulations regarding the disposal of coal combustion residuals (CCR) in landfills and surface impoundments (40 CFR 257.90-257.98, "CCR rule"), detection monitoring events were completed on August 23, 2017 and December 21, 2017 at the Landfill (LF), an existing CCR unit at the H.W. Pirkey Power Plant located in Hallsville, Texas.

Eight background monitoring events were conducted at the Pirkey LF prior to these detection monitoring events, and upper prediction limits (UPLs) were calculated for each Appendix III parameter to represent background values. A lower prediction limit (LPL) was also calculated for pH. Details on the calculation of these background values are described in Geosyntec's *Statistical Analysis Summary* report, dated January 3, 2018.

To achieve an acceptably high statistical power while maintaining a site-wide false-positive rate (SWFPR) of 10% per year or less, prediction limits were calculated based on a one-of-two retesting procedure. With this procedure, a statistically significant increase (SSI) is only concluded if both samples in a series of two exceeds the UPL. In practice, if the initial result did not exceed the UPL, a second sample was not collected or analyzed.

Detection monitoring results and the relevant background values are summarized in Table 1b.

- Boron concentrations exceeded the intrawell UPL of 0.03 mg/L in both the initial (0.0402 mg/L) and second (0.0450 mg/L) samples collected at AD-23. Therefore, an SSI over background is concluded for boron at AD-23.

- Total dissolved solids (TDS) concentrations exceeded the interwell UPL of 335 mg/L in both the initial (1128 mg/L) and second (1260 mg/L) samples collected at AD-34. Therefore, an SSI over background is concluded for TDS at AD-34.

- Sulfate concentrations exceeded the interwell UPL of 207 mg/L in both the initial (1231 mg/L) and second (1020 mg/L) samples collected at AD-34. Therefore, an SSI over background is concluded for sulfate at AD-34.

As a result, the Pirkey LF CCR unit will conduct an alternate source demonstration.

No other exceedances of UPLs were observed during these detection monitoring events.

The following modifications to Geosyntec’s *Statistical Analysis Summary* report were incorporated after the certification date of January 3, 2018:

- Table 1 (“Groundwater Data Summary”) was revised to reflect appropriate significant digits for estimated (J-flagged) values; and,

- Figure E (“Analysis of Variance”) of Attachment A (“Statistical Analysis Output”) was revised to correct a formatting error.

* * * * *

CERTIFICATION BY QUALIFIED PROFESSIONAL ENGINEER

I certify that the selected statistical method, described above and in the January 3, 2018 *Statistical Analysis Summary* report, is appropriate for evaluating the groundwater monitoring data for the Pirkey LF CCR management area and that the requirements of 40 CFR 257.93(f) have been met.

GROUNDWATER STATS
CONSULTING

November 4, 2017

Geosyntec Consultants
Attn: Mr. Bruce Sass
150 E. Wilson Bridge Rd., #232
Worthington, OH 43085

Dear Mr. Sass,

Groundwater Stats Consulting, formerly the statistical consulting division of Sanitas Technologies, is pleased to provide the screening and statistical analysis of background groundwater data for American Electric Power's Pirkey Landfill. The analysis complies with the federal rule for the Disposal of Coal Combustion Residuals from Electric Utilities (CCR Rule, 2015) as well as with the USEPA Unified Guidance (2009).

Sampling began at Pirkey Landfill for the CCR program in 2016, and 8 background samples have been collected at each of the groundwater monitoring wells. The monitoring well network, as provided by Geosyntec Consultants, consists of the following: upgradient AD-8, AD-12, AD-16, and AD-27; and downgradient wells AD-23, AD-34, and AD-35.

Data were sent electronically to Groundwater Stats Consulting, and the statistical analysis was reviewed by Dr. Kirk Cameron, PhD Statistician with MacStat Consulting, primary author of the USEPA Unified Guidance, and Senior Advisor to Groundwater Stats Consulting.

The following constituents were evaluated: Appendix III parameters – boron, calcium, chloride, fluoride, pH, sulfate, and TDS; and Appendix IV parameters - antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, combined radium 226 & 228, fluoride, lead, lithium, mercury, molybdenum, selenium, and thallium.

Time series plots for Appendix III and IV parameters at all wells are provided for the purpose of screening data at these wells (Figure A). Additionally, box plots are included for all constituents at upgradient and downgradient wells (Figure B). The time series plots are used to initially screen for suspected outliers and trends, while the box plots provide visual representation of variation within individual wells and between all wells.

Data at all wells were evaluated for the following: 1) outliers; 2) trends; 3) most appropriate statistical method for Appendix III parameters based on site characteristics of groundwater data upgradient of the facility; and 4) eligibility of downgradient wells when intrawell statistical methods are recommended. Power curves are provided to demonstrate that the selected statistical methods for Appendix III parameters comply with the USEPA Unified Guidance recommendations as discussed below.

Summary of Statistical Method:

1) Intrawell prediction limits, combined with a 1-of-2 resample plan for boron, calcium, chloride, and fluoride;
2) Interwell prediction limits combined with a 1-of-2 resample plan for pH, sulfate, and TDS.

Parametric prediction limits are utilized when the screened historical data follow a normal or transformed-normal distribution. When data cannot be normalized or the majority of data are nondetects, a nonparametric test is utilized. The distribution of data is tested using the Shapiro-Wilk/Shapiro-Francia test for normality. After testing for normality and performing any adjustments as discussed below (US EPA, 2009), data are analyzed using either parametric or non-parametric prediction limits.

- No statistical analyses are required on wells and analytes containing 100% nondetects (USEPA Unified Guidance, 2009, Chapter 6).
- When data contain <15% nondetects in background, simple substitution of one-half the reporting limit is utilized in the statistical analysis. The reporting limit utilized for nondetects is the practical quantification limit (PQL) as reported by the laboratory.
- When data contain between 15-50% nondetects, the Kaplan-Meier nondetect adjustment is applied to the background data. This technique adjusts the mean and standard deviation of the historical concentrations to account for concentrations below the reporting limit.
- Nonparametric prediction limits are used on data containing greater than 50% nondetects.

Background Screening

Outlier Evaluation

Time series plots are used to identify suspected outliers, or extreme values that would result in limits that are not conservative from a regulatory perspective, in proposed background data. Suspected outliers at all wells for Appendix III and Appendix IV parameters were formally tested using Tukey's box plot method and, when identified, flagged in the computer database with "o" and deselected prior to construction of statistical limits (Figure C).

Tukey's outlier test noted a couple outliers as may be seen on the Outlier Summary Table and accompanying graphs. Any values identified as outliers are plotted in a lighter font on the time series graph. While the test identified a few outliers for mercury in upgradient wells, no values were flagged at this time as all results are very low level concentrations. No values were flagged as outliers for pH in upgradient wells, as all concentrations appear to represent natural variation in groundwater upgradient of the facility. For fluoride in upgradient well AD-12 and lithium in downgradient well AD-23, only the identified high outliers were flagged at this time as the low outliers are trace (or estimated) values reported between the method detection limit (MDL) and the reporting limit (RL). A substitution of the most recent reporting limit was applied when varying detection limits existed in data.

No true seasonal patterns were observed on the time series plots for any of the detected data; therefore, no deseasonalizing adjustments were made to the data. When seasonal patterns are observed, data may be deseasonalized so that the resulting limits will correctly account for the seasonality as a predictable pattern rather than random variation or a release.

While trends may be visual, a quantification of the trend and its significance is needed. The Sen's Slope/Mann Kendall trend test was used to evaluate all data at each well to identify statistically significant increasing or decreasing trends (Figure D). In the absence of suspected contamination, significant trending data are typically not included as part of the background data used for construction of prediction limits. This step serves to eliminate the trend and, thus, reduce variation in background. When statistically significant decreasing trends are present, earlier data are evaluated to determine whether earlier concentration levels are significantly different than current reported concentrations and will be deselected as necessary. When the historical records of data are truncated for the reasons above, a summary report will be provided to show the date ranges used in construction of the statistical limits.

The results of the trend analyses showed one statistically significant decreasing trend for mercury as may be seen on the Trend Test Summary Table that accompanies the trend tests. This trend is relatively low in magnitude when compared to average concentrations; therefore, no adjustments were made to the data sets.

Appendix III – Determination of Spatial Variation

The Analysis of Variance (ANOVA) was used to statistically evaluate differences in average concentrations among upgradient wells, which assists in identifying the most appropriate statistical approach (Figure E). Interwell tests, which compare downgradient well data to statistical limits constructed from pooled upgradient well data, are appropriate when average concentrations are similar across upgradient wells. Intrawell tests, which compare compliance data from a single well to screened historical data within the same well, are appropriate when upgradient wells exhibit spatial variation; when statistical limits constructed from upgradient wells would not be conservative from a regulatory perspective; and when downgradient water quality is unimpacted compared to upgradient water quality for the same parameter.

The ANOVA identified variation among upgradient well data for all of the Appendix III parameters except pH, making this parameter eligible for interwell prediction limits. All other Appendix III data were further evaluated as described below for the appropriateness of intrawell testing to accommodate the groundwater quality. A summary table of the ANOVA results is included with the reports.

Appendix III - Statistical Limits

Intrawell limits constructed from carefully screened background data from within each well serve to provide statistical limits that are conservative (i.e. lower) from a regulatory perspective, and that will rapidly identify a change in more recent compliance data from within a given well. This statistical method removes the element of variation from across wells and eliminates the chance of mistaking natural spatial variation for a release from the facility. Prior to performing intrawell prediction limits, several steps are required to reasonably demonstrate downgradient water quality does not have existing impacts from the practices of the facility.

Exploratory data analysis was used as a general comparison of concentrations in downgradient wells for all Appendix III parameters recommended for intrawell analyses to concentrations reported in upgradient wells. Upper tolerance limits are used in conjunction with confidence intervals to determine whether the estimated averages in downgradient wells are higher than observed levels upgradient of the facility. The upper tolerance limits were constructed to represent the extreme upper range of possible background levels at the site.

In cases where downgradient average concentrations are higher than observed concentrations upgradient for a given constituent, an independent study and hydrogeological investigation would be required to identify local geochemical conditions and expected groundwater quality for the region to justify an intrawell approach. Such an assessment is beyond the scope of services provided by Groundwater Stats Consulting. When there is not an obvious explanation for observed concentration differences in downgradient wells relative to reported concentrations in upgradient wells, interwell prediction limits will initially be selected for the statistical method until further evidence shows that concentrations are due to natural variation rather than a result of the facility.

Parametric tolerance limits were constructed with a target of 99% confidence and 95% coverage using pooled upgradient well data for each of the Appendix III parameters recommended for intrawell analyses (Figure F). The confidence and coverage levels for nonparametric tolerance limits are dependent upon the number of background samples. As more data are collected, the background population is better represented and the confidence and coverage levels increase.

Confidence intervals were constructed on downgradient wells for each of the Appendix III parameters using the tolerance limits discussed above, to determine intrawell eligibility for parameters with spatial variation among upgradient wells (Figure G). When the entire confidence interval is above a background standard for a given parameter, interwell methods are initially recommended as the statistical method. Therefore, only parameters with confidence intervals which did not exceed background standards are eligible for intrawell prediction limits.

Confidence intervals for the above parameters were found to be within their respective background limit for boron, calcium, chloride, and fluoride; while the confidence intervals for sulfate and TDS were above the background standards. Therefore, intrawell methods are recommended for boron, calcium, chloride, and fluoride. Interwell methods are initially recommended for sulfate and TDS, and pH which was determined to have no variation among upgradient well data. As mentioned earlier, if a demonstration supports natural variation in groundwater, intrawell methods will be considered for all parameters.

All available data through April 2017 for calcium at each well were used to establish intrawell background limits based on a 1-of-2 resample plan that will be used for future comparisons (Figure H). Interwell prediction limits, combined with a 1-of-2 resample plan, were constructed from upgradient wells for parameters discussed above (Figure I). Downgradient measurements will be compared to these background limits during each subsequent semi-annual sampling event.

Natural systems continuously evolve due to physical changes made to the environment. Examples include capping a landfill, paving areas near a well, or lining a drainage channel to prevent erosion. Periodic updating of background statistical limits will be necessary to accommodate these types of changes In the interwell case, newer data will be included in background when a minimum of 2 new samples per well are available. In the intrawell case, data for all wells and constituents are re-evaluated when a minimum of 4 new data points are available to determine whether earlier concentrations are representative of present-day groundwater quality. In some cases, the earlier portion of data are deselected prior to construction of limits in order to provide sensitive limits that will rapidly detect changes in groundwater quality. Even though the data are excluded from the calculation, the values will continue to be reported and shown in tables and graphs.

In the event of an initial exceedance of compliance well data, the 1-of-2 resample plan allows for collection of an additional sample to determine whether the initial exceedance is confirmed. When the resample confirms the initial exceedance, a statistically significant increase (SSI) is identified and further research would be required to identify the cause of the exceedance (i.e. impact from the site, natural variation, or an off-site source). If the resample falls within the statistical limit, the initial exceedance is considered to be a false positive result and, therefore, no further action is necessary. A summary table of the background prediction limits follows this letter.

Appendix IV – Assessment Monitoring Program

During an Assessment Monitoring program confidence intervals are constructed at all wells for detected Appendix IV parameters. A minimum of 4 samples is required to construct confidence intervals; however, 8 samples are generally recommended for better representation of the true average population. Established Maximum Contaminant Levels (MCLs) are used as the GWPS comparisons, unless background limits are higher as discussed below. Parametric confidence intervals are constructed with 99% confidence when data follow a normal or transformed-normal distribution. For all other cases, nonparametric confidence intervals are constructed, with the confidence level based on the number of samples available. The GWPS is exceeded only when the entire confidence interval exceeds its respective GWPS.

Background limits are established for the Appendix IV parameters using upper tolerance limits constructed with 95% confidence/95% coverage using pooled upgradient well data, for comparison against established MCLs. When background limits, or Alternate Contaminant Levels (ACLs), are higher than established MCLs, the CCR Rule recommends using these ACLs as the GWPS for the confidence interval comparisons. Additionally, tolerance limits are also recommended to establish ACLs for Appendix IV parameters, cobalt, lithium, and molybdenum, which do not have established MCLs. Since the scope of this project included screening and development of background limits for Appendix III Detection Monitoring statistics, comparison of the Appendix IV parameters with confidence intervals was not included in this report.

Recommendations

In summary, as a result of the background screening described in this letter, intrawell prediction limits combined with a 1-of-2 resample plan are recommended for boron, calcium, chloride, and fluoride. Interwell prediction limits combined with a 1-of-2 resample plan are recommended for pH, sulfate, and TDS. The statistical analyses will be constructed according to the USEPA Unified Guidance, based on 7 Appendix III parameters and 3 downgradient wells.

Thank you for the opportunity to assist you in the statistical analysis of groundwater quality for the Pirkey Landfill. If you have any questions or comments, please feel free to contact me.

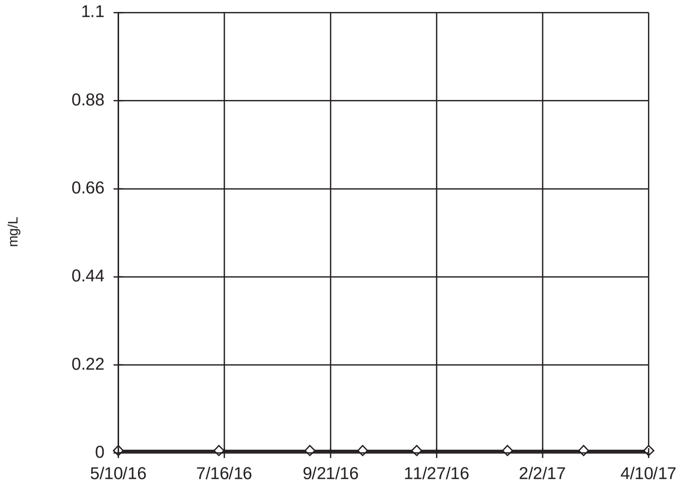
AD-34



n = 8

No outliers found. Tukey's method used in lieu of parametric test because the Shapiro Wilk normality test failed at the 0.05 alpha level.

Data were square root transformed to achieve best W statistic (graph shown in original units).

The results were invalidated, because the lower and upper quartiles are equal.

Constituent: Thallium, total Analysis Run 11/4/2017 3:07 PM View: Tukey's

Non-Parametric ANOVA

Constituent: Boron, total Analysis Run 1/15/2018 6:43 PM View: ANOVA
Pirkey LF Client: Geosyntec Data: Pirkey Landfill

For observations made between 5/10/2016 and 4/11/2017, the non-parametric analysis of variance test indicates a DIFFERENCE between the medians of the groups tested at the 5% significance level. Because the calculated Kruskal-Wallis statistic is greater than the Chi-squared value, we conclude that at least one group has a significantly different median concentration of this constituent when compared to another group.

Calculated Kruskal-Wallis statistic = 23.84

Tabulated Chi-Squared value = 7.815 with 3 degrees of freedom at the 5% significance level.

There were 3 groups of ties in the data, consequently the Kruskal-Wallis statistic (H) was adjusted. The adjusted statistic (H') was utilized to determine if the medians were equal.
Kruskal-Wallis statistic (H) = 21.28
Adjusted Kruskal-Wallis statistic (H') = 23.84

Non-Parametric ANOVA

Because the calculated Kruskal-Wallis statistic is greater than the Chi-squared value, we conclude that at least one group has a significantly different median concentration of this constituent when compared to another group.

Calculated Kruskal-Wallis statistic = 22.08

Tabulated Chi-Squared value = 7.815 with 3 degrees of freedom at the 5% significance level.

There were 3 groups of ties in the data, consequently the Kruskal-Wallis statistic (H) was adjusted. The adjusted statistic (H') was utilized to determine if the medians were equal.
Kruskal-Wallis statistic (H) = 13.83
Adjusted Kruskal-Wallis statistic (H') = 22.08

Non-Parametric ANOVA

Constituent: pH, field   Analysis Run 1/15/2018 6:44 PM   View: ANOVA
Pirkey LF   Client: Geosyntec   Data: Pirkey Landfill

For observations made between 5/10/2016 and 4/11/2017, the non-parametric analysis of variance test indicates NO DIFFERENCE between the medians of the groups tested at the 5% significance level. Because the calculated Kruskal-Wallis statistic is less than or equal to the Chi-squared value, we conclude that no group has a significantly different median concentration of this constituent when compared to another group.

Calculated Kruskal-Wallis statistic = 6.326

Tabulated Chi-Squared value = 7.815 with 3 degrees of freedom at the 5% significance level.

There were 1 groups of ties in the data, consequently the Kruskal-Wallis statistic (H) was adjusted. The adjusted statistic (H') was utilized to determine if the medians were equal.
Kruskal-Wallis statistic (H) = 6.325
Adjusted Kruskal-Wallis statistic (H') = 6.326

Parametric ANOVA

Constituent: Sulfate, total   Analysis Run 1/15/2018 6:44 PM   View: ANOVA
Pirkey LF   Client: Geosyntec   Data: Pirkey Landfill

For observations made between 5/10/2016 and 4/11/2017 the parametric analysis of variance test (after cube root transformation) indicates VARIATION at the 5% significance level. Because the calculated F statistic is greater than the tabulated F statistic, the hypothesis of a single homogeneous population is rejected.

Calculated F statistic = 193.4

Tabulated F statistic = 2.95 with 3 and 28 degrees of freedom at the 5% significance level.

ONE-WAY PARAMETRIC ANOVA TABLE

Source of Variation	Sum of Squares	Degrees of Freedom	Mean Squares	F
Between Groups	60.29	3	20.1	193.4
Error Within Groups	2.91	28	0.1039	
Total	63.2	31		

The Shapiro Wilk normality test on the residuals passed after cube root transformation. Alpha = 0.05, calculated = 0.9461, critical = 0.93. Levene's Equality of Variance test passed. Calculated = 2.341, tabulated = 2.95.

Parametric ANOVA

Appendix I

I. <u>Overview</u>

This *Annual Groundwater Monitoring Report* (Report) has been prepared to report the status of activities for the preceding year for an existing CCR unit at Southwestern Electric Power Company's, a wholly-owned subsidiary of American Electric Power Company (AEP), Pirkey Power Plant. The USEPA's CCR rules require that the Annual Groundwater Monitoring Report be posted to the operating record for the preceding year no later than January 31, 2018.

In general, the following activities were completed:

- Monitoring wells were installed and developed to establish a certified groundwater monitoring system around each CCR unit, in accordance with the requirements of 40 CFR 257.91 pursuant AEP's *Groundwater Monitoring Network Design Report (3/9/2017)*;
- Groundwater samples were collected and analyzed for Appendix III and Appendix IV constituents, as specified in 40 CFR 257.94 *et seq*. and AEP's *Groundwater Sampling and Analysis Plan (2016)*;
- Groundwater data underwent various validation tests, including tests for completeness, valid values, transcription errors, and consistent units;
- Background groundwater quality data was collected for each Appendix III and Appendix IV constituent;
- Detection Monitoring sampling was initiated;
- A statistical process in accordance with 40 CFR 257.93 to evaluate groundwater data was prepared, certified, and posted to AEP's CCR website in April 2017. AEP's *Statistical Analysis Plan (*AEP 2017). The statistical process was guided by USEPA's *Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities, Unified Guidance* ("Unified Guidance", USEPA, 2009). Data evaluation is underway.

The major components of this annual report, to the extent applicable at this time, are presented in sections that follow:

- A map, aerial photograph or a drawing showing the CCR management unit(s), all groundwater monitoring wells and monitoring well identification numbers;
- Identification of any monitoring wells that were installed or decommissioned during the preceding year, along with a statement as to why that happened;
- All of the monitoring data collected, including the rate and direction of groundwater flow, plus a summary showing the number of samples collected per monitoring well, the dates the samples were collected and whether the sample was collected as part of detection monitoring or assessment monitoring programs is included in Appendix I;

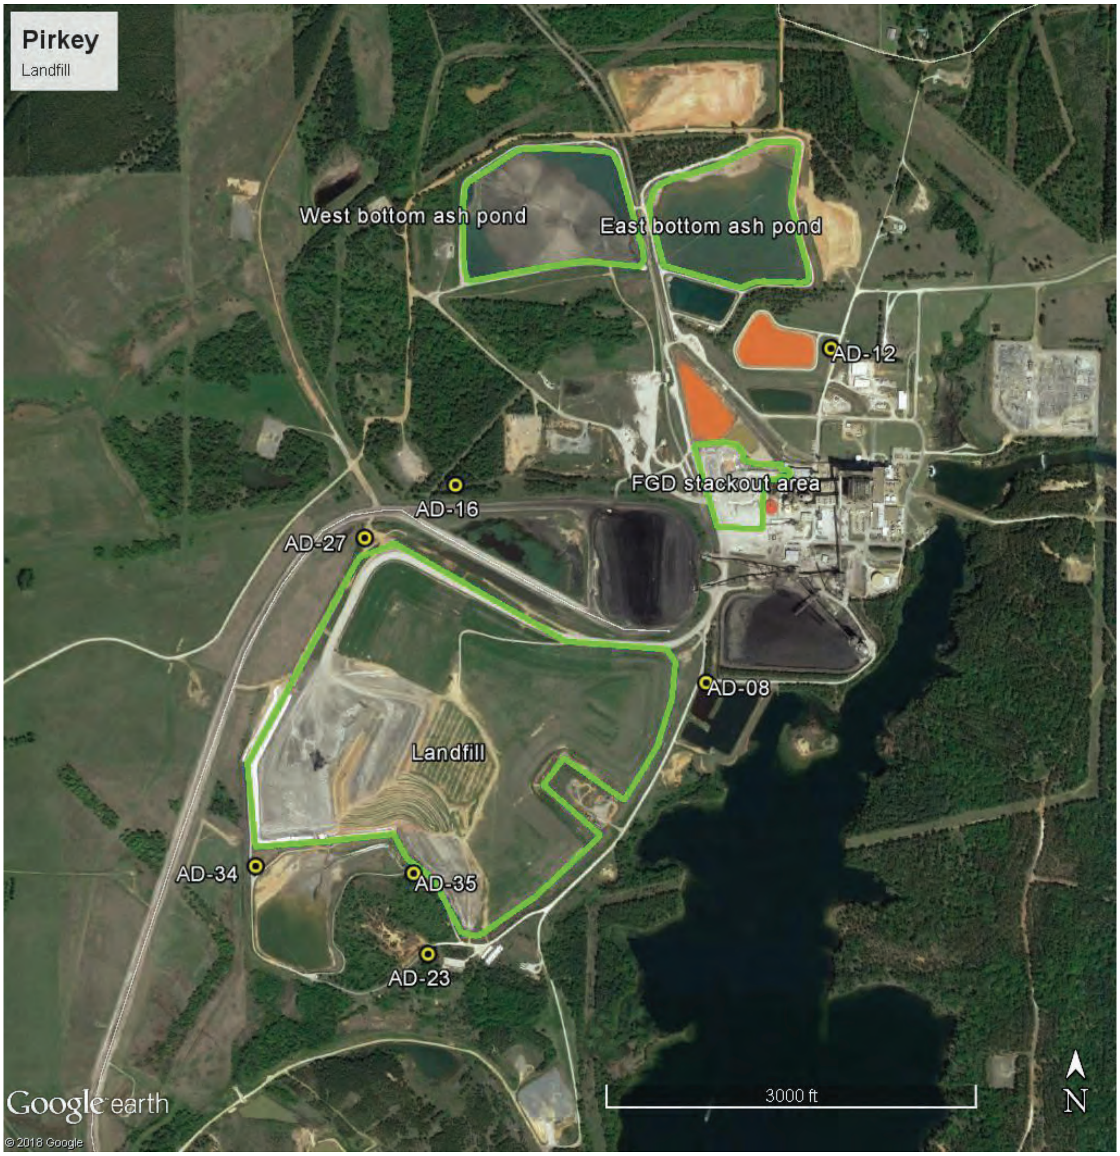
- A summary of any transition between monitoring programs or an alternate monitoring frequency, for example the date and circumstances for transitioning from detection monitoring to assessment monitoring, in addition to identifying the constituents detected at a statistically significant increase over background concentrations;
- Other information required to be included in the annual report such as alternate source demonstration or assessment of corrective measures, if applicable.

In addition, this report summarizes key actions completed, and where applicable, describes any problems encountered and actions taken to resolve those problems. The report includes a projection of key activities for the upcoming year.

II. Groundwater Monitoring Well Locations and Identification Numbers

The figure that follows depicts the PE-certified groundwater monitoring network, the monitoring well locations and their corresponding identification numbers.

Landfill Monitoring Wells	
Up Gradient	Down Gradient
AD-8	AD-23
AD-12	AD-34
AD-16	AD-35
AD-27	



III. Monitoring Wells Installed or Decommissioned

There were no monitoring wells installed or decommissioned in 2017. The network design, as summarized in the *Groundwater Monitoring Network Design Report* (3/9/2017) and as posted at the CCR web site for Pirkey Power Plant, did not change. That design report, viewable on the AEP CCR web site, discusses the facility location, the hydrogeological setting, the hydrostratigraphic units, the uppermost aquifer, downgradient monitoring well locations and the upgradient monitoring well locations.

IV. Groundwater Quality Data and Static Water Elevation Data, With Flow Rate and Direction and Discussion

Appendix I contains tables showing the groundwater quality data collected during the establishment of background quality. Static water elevation data from each monitoring event also are shown in Appendix I, along with the groundwater velocity, groundwater flow direction and potentiometric maps developed after each sampling event.

V. Discussion About Transition Between Monitoring Requirements or Alternate Monitoring Frequency

As of this first annual groundwater report date there has been no transition between detection monitoring and assessment monitoring. Detection monitoring will continue in 2018. The sampling frequency of twice per year will be maintained for the Appendix III parameters (boron, calcium, chloride, fluoride, pH, sulfate and total dissolved solids).

Regarding defining an alternate monitoring frequency, the groundwater velocity and monitoring well production is high enough at this facility that no modification of the twice-per-year detection monitoring effort is needed.

VI. Other Information Required

At the appropriate time the geochemical analyses, coupled with the statistical analyses of the groundwater quality data, will determine whether an alternate source or alternate sources are affecting groundwater chemistry. In those cases where an alternate source demonstration is made, those analyses and supporting information will be presented as well.

VII. Description of Any Problems Encountered in 2017 and Actions Taken

No significant problems were encountered. The low flow sampling effort went smoothly and the schedule was met to support this first annual groundwater report preparation.

VIII. A Projection of Key Activities for the Upcoming Year

Key activities for 2018 include:

- Detection monitoring on a twice per year schedule;
- Evaluation of the first detection monitoring results from a statistical analysis viewpoint, looking for any statistically significant increases, or decreases when pH is considered;
- Responding to any new data received in light of what the CCR rule requires;
- Preparation of the second annual groundwater report.

APPENDIX I

Tables follow, showing the groundwater monitoring data collected, the rate and direction of groundwater flow, and a summary showing the number of samples collected per monitoring well. The dates that the samples were collected also is shown.

- — Groundwater Elevation Contour
- → Approximate Groundwater Flow Direction

Notes

- Monitoring well coordinates and water level data (collected on February 28 - March 1, 2017) provided by AEP.
- Site features based on information available in CCR Groundwater Monitoring Well Network Evaluations (Arcadis, 2016) provided by AEP.
- Groundwater elevation units are feet above mean sea level.
- East and West Bottom Ash Ponds have compacted cohesive soil from elevation 344 to 347 ft. msl (Sargent and Lundy, 1984; AMEC, 2011).
- Clearwater pond base elevation is 344 ft. msl (Sargent and Lundy, 1983).

Appendix II-Statistical Analyses

Appendix III- Alternate Source Demonstration

Appendix IV- Well Installation

I. Summary

This *Annual Groundwater Monitoring Report* (Report) has been prepared to report the status of activities for the preceding year for an existing CCR unit at Southwestern Electric Power Company's, a wholly-owned subsidiary of American Electric Power Company (AEP), Pirkey Power Plant. The USEPA's CCR rules require that the Annual Groundwater Monitoring Report be posted to the operating record for the preceding year no later than January 31, 2021.

In general, the following activities were completed:

- Groundwater samples were collected for the wells the landfill groundwater monitoring network in June and November 2020 and analyzed for Appendix III, as specified in 40 CFR 257.94 *et seq.* and AEP's *Groundwater Sampling and Analysis Plan (2016)*;
- Groundwater data underwent various validation tests, including tests for completeness, valid values, transcription errors, and consistent units;
- An alternate source for the statistically significant increases (SSIs) over background that caused this unit to transition to assessment monitoring was identified in a report (*Alternative Source Demonstration Report Federal CCR Rule*) on January 7, 2020. As a result, the unit returned to detection monitoring and was in detection monitoring at the beginning of 2020;
- The unit was in detection monitoring at the end of 2020;
- There were no SSIs determined for the 2nd half 2019 groundwater sampling and analysis event;
- SSI over background was determined for fluoride at well AD-34 on October 2, 2020. An alternate source for fluoride exceedance was identified in a report (*Alternative Source Demonstration Report Federal CCR Rule*) on December 31, 2020;
- The November sampling event is undergoing statistical analysis;
- Groundwater Monitoring Statistical Evaluation Reports to evaluate groundwater data were prepared and certified in accordance with 40 CFR 257.93. The statistical process was guided by USEPA's *Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities, Unified Guidance* ("Unified Guidance", USEPA, 2009).

The major components of this annual report, to the extent applicable at this time, are presented in sections that follow:

- A map, aerial photograph or a drawing showing the CCR management unit(s), all groundwater monitoring wells and monitoring well identification numbers;
- Identification of any monitoring wells that were installed or decommissioned during the preceding year, along with a statement as to why that happened;

- All of the monitoring data collected, including the rate and direction of groundwater flow, plus a summary showing the number of samples collected per monitoring well, the dates the samples were collected and whether the sample was collected as part of detection monitoring or assessment monitoring programs is included in **Appendix I**;
- A summary of any transition between monitoring programs or an alternate monitoring frequency, for example the date and circumstances for transitioning from detection monitoring to assessment monitoring, in addition to identifying the constituents detected at a statistically significant increase over background concentrations, if applicable.
- Other information required to be included in the annual report such as alternate source demonstration or assessment of corrective measures, if applicable.

In addition, this report summarizes key actions completed, and where applicable, describes any problems encountered and actions taken to resolve those problems. The report includes a projection of key activities for the upcoming year.

II. Groundwater Monitoring Well Locations and Identification Numbers

The figure that follows depicts the PE-certified groundwater monitoring network, the monitoring well locations and their corresponding identification numbers.

Landfill Monitoring Wells	
Up Gradient	Down Gradient
AD-8	AD-23
AD-12	AD-34
AD-16	AD-35 (decommissioned 2018)
AD-27	AD-36 (installed 2019)

III. Monitoring Wells Installed or Decommissioned

One monitoring well (AD-7R) was installed to better understand spatial variability of constituents across the site, groundwater flow, and groundwater chemistry. The well installation report can be found in **Appendix IV**.

IV. Groundwater Quality Data and Static Water Elevation Data, With Flow Rate and Direction and Discussion

Appendix I contains tables showing the groundwater quality. Static water elevation data from each monitoring event also are shown in **Appendix I**, along with the groundwater velocity, groundwater flow direction and potentiometric maps developed after each sampling event.

As required by the detection monitoring rules, 40 CFR 257.94 et seq., two rounds of sampling were conducted in June and November including all Appendix III parameters.

The verification sample after the 2nd half 2019 groundwater sampling event appeared to be consistent with groundwater flow that is normally seen near the landfill (toward the south).

The verification sample after the 1st half 2020 groundwater sampling event appeared to be consistent with groundwater flow that is normally seen near the landfill (toward the south).

Detection monitoring will continue in 2021.

V. Statistical Evaluation of 2020 Events

The three statistical analysis reports available for this reporting period are included in **Appendix II**.

There were no SSIs determined for the 2nd half 2019 groundwater sampling and analysis event.

SSI over background was determined for fluoride at well AD-34 on October 2, 2020.

Data from the events conducted between August 2017 and June 2020, including both initial and verification results, were evaluated for inclusion in the background dataset. Additionally, data from eight background monitoring events at AD-36, which was installed to replace well AD-35 following its decommissioning, were evaluated to establish background concentrations for Appendix III constituent. Documentation for this information can be found in a report dated January 27, 2021 (*STATISTICAL ANALYSIS SUMMARY-Background Update Calculations H.W. Pirkey Power Plant Landfill*).

The November sampling event is undergoing statistical analysis.

VI. Alternate Source Demonstration

An alternate source investigation was conducted for the landfill's SSIs over background. An alternate source for the SSIs over background that caused to unit to transition to assessment monitoring was identified in a report (*Alternative Source Demonstration Report Federal CCR Rule*) on January 7, 2020. As a result, the unit returned to detection monitoring.

SSI over background was determined for fluoride on October 2, 2020. An alternate source demonstration was identified in a report (*Alternative Source Demonstration Report Federal CCR Rule*) on December 31, 2020.

Documentation supporting these findings are found in **Appendix III**.

VII. Discussion About Transition Between Monitoring Requirements or Alternate Monitoring Frequency

On April 3, 2018, no alternate source was found for SSIs over background, so the unit transitioned to assessment monitoring. On December 26, 2019, SSLs above GWPS were identified. On March 26, 2019, no alternate sources were identified for the unit, so it transitioned into assessment of corrective measures. On April 22, 2019, an alternate source was identified for the SSLs, so the unit did not continue assessment of corrective measures work and remained in assessment monitoring.

On January 7, 2020, an alternate source was found for the SSIs determined for boron, total dissolved solids (TDS), and sulfate as summarized in *Groundwater Monitoring Statistical Evaluation Report* (1/3/2018), so the unit returned to detection monitoring. The unit remained in detection monitoring during 2020.

Detection monitoring will continue in 2021.

Regarding defining an alternate monitoring frequency, no modification of the twice-per-year detection monitoring effort is needed.

VIII. Other Information Required

No other information applies at this time.

IX. Description of Any Problems Encountered in 2020 and Actions Taken

No problems were encountered this year.

X. A Projection of Key Activities for the Upcoming Year

Key activities for the next year include:

- Detection monitoring sampling will be conducted;

- Evaluation of the detection monitoring results from a statistical analysis viewpoint, looking for any SSIs over background;
- Responding to any new data received in light of CCR rule requirements;
- Preparation of the next annual groundwater report.

APPENDIX I

Tables follow, showing the groundwater monitoring data collected, the rate and direction of groundwater flow, and a summary showing the number of samples collected per monitoring well. The dates that the samples were collected also is shown.

Subject: Evaluation of Detection Monitoring Data at Pirkey Plant's Landfill

---

In accordance with the United States Environmental Protection Agency's (USEPA's) regulations regarding the disposal of coal combustion residuals (CCR) in landfills and surface impoundments (40 CFR 257 Subpart D, "CCR rule"), the second semi-annual detection monitoring event of 2019 at the Landfill, an existing CCR unit at the Pirkey Power Plant located in Hallsville, Texas, was completed on August 13, 2019. Based on the results, a two-of-two verification sampling was completed on January 27, 2020.

Eight background monitoring events were conducted at the Pirkey LF prior to these detection monitoring events, and upper prediction limits (UPLs) were calculated for each Appendix III parameter to represent background values. Lower prediction limits (LPLs) were also calculated for pH. Details on the calculation of these background values are described in Geosyntec's *Statistical Analysis Summary* report, dated January 3, 2018. An alternative source demonstration (ASD) was certified on January 7, 2020 which resulted in a revision from interwell tests to intrawell tests for the pH, sulfate, and TDS prediction limits.

To achieve an acceptably high statistical power while maintaining a site-wide false-positive rate (SWFPR) of 10% per year or less, prediction limits were calculated based on a one-of-two retesting procedure. With this procedure, a statistically significant increase (SSI) is only concluded if both samples in a series of two exceeds the UPL (or are below the LPL for pH). In practice, if the initial result did not exceed the UPL, a second sample was not collected or analyzed.

Detection monitoring results and the relevant background values are compared in Table 1. No SSIs were observed at the Pirkey Landfill CCR unit, and as a result the Pirkey Landfill will remain in detection monitoring.

The statistical analysis was conducted within 90 days of completion of sampling and analysis in accordance with 40 CFR 257.93(h)(2). A certification of these statistics by a qualified professional engineer is provided in Attachment A.

Memorandum

Date:	October 2, 2020
To:	David Miller (AEP)
Copies to:	Leslie Fuerschbach (AEP)
From:	Allison Kreinberg (Geosyntec)
Subject:	Evaluation of Detection Monitoring Data at Pirkey Plant's Landfill

In accordance with the United States Environmental Protection Agency's (USEPA's) regulations regarding the disposal of coal combustion residuals (CCR) in landfills and surface impoundments (40 CFR 257 Subpart D, "CCR rule"), the first semi-annual detection monitoring event of 2020 at the Landfill, an existing CCR unit at the Pirkey Power Plant located in Hallsville, Texas, was completed on June 3, 2020. Based on the results, a two-of-two verification sampling was completed on July 15, 2020.

Eight background monitoring events were conducted at the Pirkey LF prior to these detection monitoring events, and upper prediction limits (UPLs) were calculated for each Appendix III parameter to represent background values. Lower prediction limits (LPLs) were also calculated for pH. Details on the calculation of these background values are described in Geosyntec's *Statistical Analysis Summary* report, dated January 3, 2018. An alternative source demonstration (ASD) was certified on January 7, 2020 which resulted in a revision from interwell tests to intrawell tests for the pH, sulfate, and TDS prediction limits.

To achieve an acceptably high statistical power while maintaining a site-wide false-positive rate (SWFPR) of 10% per year or less, prediction limits were calculated based on a one-of-two retesting procedure. With this procedure, a statistically significant increase (SSI) is only concluded if both samples in a series of two exceeds the UPL (or are below the LPL for pH). In practice, if the initial result did not exceed the UPL, a second sample was not collected or analyzed.

Detection monitoring results and the relevant background values are compared in Table 1 and noted exceedances are described in the list below.

- Fluoride concentrations exceeded the intrawell UPL of 1.00 mg/L in both the initial (1.22 mg/L) and second (1.39 mg/L) samples collected at AD-34. Therefore, an SSI over background is concluded for fluoride at AD-34.

In response to the exceedances noted above, the Pirkey LF CCR unit will either transition to assessment monitoring or an alternative source demonstration (ASD) for fluoride will be conducted in accordance with 40 CFR 257.94(e)(2). If the ASD is successful, the Pirkey LF will remain in detection monitoring.

The statistical analysis was conducted within 90 days of completion of sampling and analysis in accordance with 40 CFR 257.93(h)(2). A certification of these statistics by a qualified professional engineer is provided in Attachment A.

SECTION 1

EXECUTIVE SUMMARY

In accordance with the United States Environmental Protection Agency's (USEPA's) regulations regarding the disposal of coal combustion residuals (CCR) in landfills and surface impoundments (40 CFR Subpart D, "CCR rule"), groundwater monitoring has been conducted at the lined landfill (LF), an existing CCR unit at the H.W. Pirkey Power Plant located in Hallsville, Texas.

Eight monitoring events were completed prior to May 2017 to establish background concentrations for Appendix III and Appendix IV constituents under the CCR rule. A detection monitoring event was conducted in August 2017 with verification samples collected in December 2017. During the August 2017 monitoring event, statistically significant increases (SSIs) for boron, sulfate, and total dissolved solids (TDS) were observed, and the unit transitioned to assessment monitoring. Semiannual assessment monitoring events were conducted between March 2018 and May 2019. An ASD was prepared in 2020 that indicated that:

- Former mining activities in the vicinity of the LF (shown as 'A Area' in Figure 1) were affecting groundwater quality at monitoring well AD-34;
- Interwell statistics were not appropriate for the Pirkey LF; and,
- The unit could return to detection monitoring (Geosyntec, 2020a).

Since returning to detection monitoring, two detection monitoring events have been completed ([1] August 2019 with verification samples collected in January 2020 and [2] June 2020).

Data from the events conducted between August 2017 and June 2020, including both initial and verification results, were evaluated for inclusion in the background dataset. Additionally, data from eight background monitoring events at AD-36, which was installed to replace well AD-35 following its decommissioning, were evaluated to establish background concentrations for Appendix III constituents. Groundwater data underwent several validation tests, including those for completeness, sample tracking accuracy, transcription errors, and consistent use of measurement units. No data quality issues were identified which would impact the usability of the data.

The data were submitted to Groundwater Stats Consulting, LLC for statistical analysis. The compliance data were reviewed for outliers, which were removed (when appropriate) prior to updating prediction limits for Appendix III constituents to represent background values at AD-23 and AD-34 and establishing background at AD-36. Oversight on the use of statistical calculations was provided by Dr. Jim Loftis, senior advisor at GSC. Certification of the selected statistical methods by a qualified professional engineer is documented in Attachment A.

SECTION 2

LANDFILL EVALUATION

2.1 Previous Background Calculations

Eight background monitoring events were completed from May 2016 through April 2017 to establish background concentrations for Appendix III and Appendix IV constituents under the CCR rule. The data were reviewed for outliers and trends prior to calculating UPLs for the Appendix III constituents. A lower prediction limit (LPL) was also established for pH. Interwell prediction limits were selected for pH, sulfate, and TDS, and intrawell prediction limits were selected for boron, calcium, chloride, and fluoride. Both the interwell and intrawell tests used a one-of-two resampling plan. The statistical analyses to establish background levels were previously documented in the February 2018 *Statistical Analysis Summary* report (Geosyntec, 2018).

The Pirkey LF transitioned to assessment monitoring following completion of the August 2017 detection monitoring event. Semiannual assessment monitoring events were completed between March 2018 and May 2019 in accordance with 40 CFR 257.95. Following the collection of additional data in the vicinity of the LF in 2019, the conceptual site model was updated. It was determined that former mining activities in the vicinity of the LF (shown as ‘A Area’ in Figure 1) were affecting groundwater quality at monitoring well AD-34 (Geosyntec, 2020a). Thus, interwell prediction limits are not appropriate for the detection monitoring. The unit returned to detection monitoring, and intrawell prediction limits were calculated to reflect the variability in the site conditions.

Monitoring well AD-35 was decommissioned in November 2018 due to landfill expansion activities. AD-35 was replaced by a new downgradient monitoring well, AD-36, which was installed in April 2019 and added to the monitoring network. Eight samples were collected between August 2019 and July 2020 to establish Appendix III background values at AD-36 in accordance with the CCR Rule.

2.2 Data Validation & QA/QC

After the last background monitoring event in 2017, three semiannual detection monitoring events and four semiannual assessment monitoring events were conducted at the LF. If the initial results from a detection monitoring event identified possible exceedances, verification sampling was completed on an individual well/constituent basis. Samples were analyzed for the Appendix III constituents during the semiannual assessment monitoring events; thus, a minimum of four samples were collected from each compliance well since the last background update. A summary of data collected at existing wells AD-23 and AD-34 during these detection and assessment monitoring events may be found in Table 1. A summary of the data collected at new well AD-36 during the eight background monitoring events may be found in Table 2.

Chemical analysis was completed by an analytical laboratory certified by the National Environmental Laboratory Accreditation Program (NELAP). Quality assurance and quality control (QA/QC) samples completed by the analytical laboratory included the use of laboratory reagent blanks (LRBs), continuing calibration verification (CCV) samples, and laboratory fortified blanks (LFBs).

The analytical data were imported into a Microsoft Access database, where checks were completed to assess the accuracy of sample location identification and analyte identification. Where necessary, unit conversions were applied to standardize reported units across all sampling events. Exported data files were created for use with the Sanitas™ v.9.6.27 statistics software. The export was checked against the analytical data for transcription errors and completeness. No QA/QC issues were noted which would impact data usability.

2.3 Statistical Analysis

The data used to conduct the statistical analyses described below are summarized in Table 1 and Table 2. Statistical analyses for the LF were conducted in accordance with the October 2020 *Statistical Analysis Plan* (Geosyntec, 2020b), except where noted below. The complete statistical analysis results are included in Attachment B.

Time series plots of Appendix III constituents are included in Attachment B and were used to evaluate concentrations over time and to provide an initial screening of suspected outliers and trends. Box plots were also compiled to provide visual representation of variations between wells and within individual wells (Attachment B).

2.3.1 Outlier Evaluation

Potential outliers were evaluated using Tukey’s outlier test; i.e., data points were considered potential outliers if they met one of the following criteria:

$$x_i < \tilde{x}_{0.25} - 3 \times IQR \quad (1)$$

or

$$x_i > \tilde{x}_{0.75} + 3 \times IQR \quad (2)$$

where:

$x_i =$ individual data point
$\tilde{x}_{0.25} =$ first quartile
$\tilde{x}_{0.75} =$ third quartile
$IQR =$ the interquartile range $= \tilde{x}_{0.75} - \tilde{x}_{0.25}$

Tukey’s outlier test indicated select values for boron and sulfate at upgradient well AD-27 and TDS at upgradient well AD-8 could be considered outliers. Additionally, the August 13, 2019 chloride value at AD-36 and TDS value at AD-23 could be considered outliers. However, these values were not removed from the dataset as they appeared to represent variation in natural groundwater concentrations (Attachment B).

2.3.2 AD-23 and AD-34 Prediction Limit Update

2.3.2.1 Establishment of Updated Background Dataset

Analysis of variance (ANOVA) was conducted during the initial background screening to assist in identifying if intrawell tests are the most appropriate statistical approach for assessing Appendix III constituents. Intrawell tests compare compliance data from a single well to background data within the same well and are most appropriate (1) when upgradient wells exhibit spatial variation; (2) when statistical limits constructed from upgradient wells would not be conservative from a regulatory perspective; or (3) when downgradient water quality is not impacted compared to upgradient water quality for the same constituent. Intrawell tests were used to evaluate potential SSIs for boron, calcium, chloride, and fluoride. Interwell tests were originally used to evaluate potential SSIs for pH, sulfate, and TDS. However, because former mining activities in the vicinity of the LF affect groundwater quality at monitoring well AD-34 (Geosyntec, 2020a), intrawell tests will be used to evaluate potential SSIs for all Appendix III constituents moving forward.

Periodic updating of background statistical limits is necessary as natural systems continuously change due to physical changes to the environment. For intrawell analyses, data for all wells and constituents are re-evaluated when a minimum of four new data points are available. These four (or more) new data points are used to compare against the existing background dataset.

Mann-Whitney (Wilcoxon rank-sum) tests were used to compare the medians of historical data (May 2016 – April 2017) to the new compliance samples (August 2017 – June 2020 [July 2020 for fluoride, TDS, and pH at AD-34]). Results were evaluated to determine if the medians of the two groups were similar at the 99% confidence level. Where no significant difference was found, the new compliance data were added to the background dataset. Where a statistically significant difference was found between the medians of the two groups, the data were reviewed to evaluate the cause of the difference and to determine if adding newer data to the background dataset, replacing the background dataset with the newer data, or continuing to use the existing background dataset was most appropriate. If the differences appeared to have been caused by a release, then the previous background dataset would have continued to be used.

The complete Mann-Whitney test results and a summary of the significant findings can be found in Attachment B. Statistically significant differences were found for calcium in upgradient well AD-16, chloride in upgradient wells AD-16 and AD-27, and pH at upgradient well AD-16. The more recent calcium values at AD-16 are lower than the initial background dataset, whereas the more recent chloride values at AD-16 and AD-27 are slightly higher than the initial background dataset. While the more recent chloride values at AD-16 and AD-27 are slightly higher than the initial background dataset, concentrations at both wells are still low and generally consistent with values at other wells in the network. Because AD-16 and AD-27 are upgradient wells and represent natural variability upgradient of the unit, the earlier sample results were deselected so that only the most recent eight data points will be used for calcium at AD-16 and chloride at AD-16 and AD-27. For pH at AD-16, the recent concentrations were only slightly higher than the initial dataset and all values were used in the prediction limit calculations. Because intrawell prediction limits are used for all Appendix III constituents, the selection of background datasets at upgradient wells will not affect the calculation of background prediction limits.

2.3.2.2 Updated Prediction Limits

After the revised background dataset was established, a parametric or non-parametric analysis was selected based on the distribution of the data and the frequency of non-detect data. Estimated results less than the practical quantitation limit (PQL) – i.e., “J-flagged” data – were considered detections and the estimated results were used in the statistical analyses. Non-parametric analyses were selected for datasets with at least 50% non-detect data or datasets that could not be normalized. Parametric analyses were selected for datasets (either transformed or untransformed) that passed the Shapiro-Wilk / Shapiro-Francía test for normality. The Kaplan-Meier non-detect adjustment was applied to datasets with between 15% and 50% non-detect data. For datasets with fewer than 15% non-detect data, non-detect data were replaced with one half of the PQL. The selected analysis (i.e., parametric or non-parametric) and transformation (where applicable) for each background dataset are shown in Attachment B.

Intrawell UPLs were updated using all the historical data through June 2020 to represent background values for all Appendix III constituents at AD-23 and AD-24. The verification sample collected for fluoride, pH, and TDS at AD-34 in July 2020 was also included in the background update. Intrawell LPLs were also updated for pH. The updated prediction limits are summarized in Table 3.

The intrawell UPLs were calculated for a one-of-two retesting procedure; i.e., if at least one sample in a series of two does not exceed the UPL, then it can be concluded that an SSI has not occurred. In practice, where the initial result does not exceed the UPL, a second sample will not be collected. The retesting procedures allowed achieving an acceptably high statistical power to detect changes at downgradient wells for constituents evaluated using intrawell prediction limits.

2.3.3 AD-36 Prediction Limit Establishment

As eight groundwater sampling events have been completed at AD-36, which was recently added to the well network, prediction limits were established for Appendix III constituents using those eight events as the background dataset. The same approach outlined in Section 2.3.2.2 was used for the AD-36 dataset. Additionally, trend tests were completed to evaluate if significant trends were present at AD-36. No significant trends were identified for Appendix III constituents at AD-36 (Appendix A).

Intrawell UPLs were calculated using the complete background dataset to represent background values for all Appendix III constituents at AD-36. Intrawell LPLs were also updated for pH. The updated prediction limits are summarized in Table 3. The intrawell UPLs were calculated for a one-of-two retesting procedure. The retesting procedures allowed achieving an acceptably high statistical power to detect changes at downgradient wells for constituents evaluated using intrawell prediction limits.

2.4 Conclusions

Semiannual detection or assessment monitoring events have been completed at AD-23 and AD-34 in accordance with the CCR Rule since May 2017. Eight background events have been completed at AD-36 in accordance with the CCR Rule since August 2019. The laboratory and field data from these events were reviewed prior to statistical analysis, with no QA/QC issues identified that impacted data usability. At AD-23 and AD-34, Mann-Whitney tests were completed to evaluate whether data from the detection monitoring events could be added to the existing background datasets. The background datasets were updated, and UPLs and LPLs were recalculated using intrawell prediction limits with a one-of-two retesting procedure for all Appendix III constituents. At AD-36, the background dataset was established, and UPLs and LPLs were calculated using intrawell prediction limits with a one-of-two retesting procedure for all Appendix III constituents.

Re: Pirkey Landfill
Background Update – 2020

Dear Ms. Kreinberg,

Groundwater Stats Consulting, formerly the statistical consulting division of Sanitas Technologies, is pleased to provide the 2020 background update of groundwater data at American Electric Power Company's Pirkey Landfill. This site is in Detection Monitoring and the analysis complies with the federal rule for the Disposal of Coal Combustion Residuals from Electric Utilities (CCR Rule, 2015) as well as with the USEPA Unified Guidance (2009).

Sampling began at the site for the CCR program in 2016. The monitoring well network, as provided by Geosyntec Consultants, is listed below. Note that downgradient well AD-35 was originally in the well network but has been abandoned and replaced with well AD-36.

- **Upgradient wells:** AD-8, AD-12, AD-16, and AD-27
- **Downgradient wells:** AD-23, AD-34, and AD-36

Data were sent electronically, and the statistical analysis was conducted according to the Statistical Analysis Plan and screening evaluation prepared by GSC and approved by Dr. Kirk Cameron, PhD Statistician with MacStat Consulting, primary author of the USEPA Unified Guidance, and Senior Advisor to GSC. During this analysis, proposed background data from replacement well AD-36 were screened, and data from all other wells were also screened for updating background statistical limits as described below.

The CCR program consists of the following Appendix III constituents:

- boron, calcium, chloride, fluoride, pH, sulfate, and TDS

Time series plots for these parameters at all wells are provided for the purpose of screening data at these wells (Figure A). Additionally, a separate section of box plots is included for all constituents at upgradient and downgradient wells (Figure B). The time series plots are used to initially screen for suspected outliers and trends, while the box plots provide visual representation of variation within individual wells and between all wells. When values in background have been flagged as outliers, they may be seen in a lighter font and as a disconnected symbol on the graphs.

In earlier analyses, data at all wells were evaluated for the following: 1) outliers; 2) trends; 3) most appropriate statistical method for Appendix III parameters based on site characteristics of groundwater data upgradient of the facility; and 4) eligibility of downgradient wells when intrawell statistical methods are recommended. Additionally, further studies conducted by Geosyntec Consultants since the original background screening support the use of intrawell methods due to the presence of mine spoils underlying well AD-34.

Power curves are provided to demonstrate that the selected statistical methods for Appendix III parameters comply with the USEPA Unified Guidance. The EPA suggests the selected statistical method should provide at least 55% power at 3 standard deviations or at least 80% power at 4 standard deviations.

Summary of Statistical Methods:

- Intrawell prediction limits, combined with a 1-of-2 resample plan for boron, calcium, chloride, fluoride, pH, sulfate, and TDS

Parametric prediction limits are utilized when the screened historical data follow a normal or transformed-normal distribution. When data cannot be normalized or the majority of data are nondetects, a nonparametric test is utilized. While the false positive rate associated with the parametric limits is based on an annual 10% (5% per semi-annual event) as recommended by the EPA Unified Guidance (2009), the false positive rate associated with the nonparametric limits is dependent upon the available background sample size, number of future comparisons, and verification resample plan. The distribution of data is tested using the Shapiro-Wilk/Shapiro-Francia test for normality. After testing for normality and performing any adjustments as discussed below (US EPA, 2009), data are analyzed using either parametric or non-parametric prediction limits.

- No statistical analyses are required on wells and analytes containing 100% nondetects (USEPA Unified Guidance, 2009, Chapter 6).

- When data contain <15% nondetects in background, simple substitution of one-half the reporting limit is utilized in the statistical analysis. The reporting limit utilized for nondetects is the practical quantification limit (PQL) as reported by the laboratory.

- When data contain between 15-50% nondetects, the Kaplan-Meier nondetect adjustment is applied to the background data. This technique adjusts the mean and standard deviation of the historical concentrations to account for concentrations below the reporting limit.

- Nonparametric prediction limits are used on data containing greater than 50% nondetects.

Natural systems continuously evolve due to physical changes made to the environment. Examples include capping a landfill, paving areas near a well, or lining a drainage channel to prevent erosion. Periodic updating of background statistical limits is necessary to accommodate these types of changes. In the intrawell case, data for all wells and constituents may be re-evaluated when a minimum of 4 new data points are available to determine whether earlier concentrations are representative of present-day groundwater quality. In some cases, the earlier portion of data is deselected prior to construction of limits to provide sensitive limits that will rapidly detect changes in groundwater quality. Even though the data are excluded from the calculation, the values will continue to be reported and shown in tables and graphs.

Appendix III Background Update Summary – 2020

Prior to updating background data, samples were evaluated using Tukey's outlier test and visual screening through the July 2020 sample event. Tukey's outlier test only noted outliers for boron in upgradient well AD-27, chloride in well AD-36, sulfate in upgradient well AD-27, and TDS in well AD-23 and upgradient well AD-8 among the Appendix III parameters. However, none of the identified values were flagged as outliers since they appear to be representative of natural variation in groundwater quality. A summary of Tukey's test results follows this letter (Figure C).

The Sen's Slope/Mann Kendall trend test was used to evaluate all proposed background data at well AD-36 to identify statistically significant increasing or decreasing trends (Figure D). While trends may be visual, a quantification of the trend and its significance is needed. In the absence of suspected contamination, significant trending data are typically not included as part of the background data used for construction of prediction limits. The Sen's Slope/Mann Kendall trend test did not identify any statistically significant increasing or decreasing trends. A summary of those results follows this letter.

For all Appendix III parameters at all other wells besides AD-36, the Mann-Whitney (Wilcoxon Rank Sum) test was used to compare the medians of historical data through April 2017 to the new compliance samples at each well through July 2020 (Figure E). The test evaluates whether the groups are statistically different at the 99% confidence level. If no significant difference is found, background data may be updated with compliance data. The following well/constituent pairs had statistically significant higher medians in more recent data:

- Chloride: AD-16 (upgradient) and AD-27 (upgradient)
- ph: AD-16 (upgradient)

The following well/constituent pair had a statistically significant lower median in more recent data when compared to historical data:

- Calcium: AD-16 (upgradient)

Typically, when the test concludes that the medians of the two groups are significantly different, particularly in the downgradient wells, the background data are not updated to include the newer data but will be reconsidered in the future. However, since these differences occurred upgradient of the facility for each of the parameters above and represent natural variation in groundwater quality, the earlier portions of the records were deselected prior to construction of statistical limits so that limits are more representative of present-day water quality conditions. All records for these well/constituent pairs will utilize the most recent 8 measurements beginning from 4/10/2017. One exception is for pH where the most recent concentrations were only slightly higher than the earlier measurements. The test results are included with the Mann Whitney test section at the end of this report.

Intrawell prediction limits using all historical data through July 2020, except for the cases mentioned above which use truncated portions of the most recent data through July 2020, combined with a 1-of-2 resample plan, were constructed, and a summary of the updated limits follows this letter (Figure F).

Thank you for the opportunity to assist you in the statistical analysis of groundwater quality for the Pirkey Landfill. If you have any questions or comments, please feel free to contact us.

For Groundwater Stats Consulting,

Kristina Rayner

SECTION 1

INTRODUCTION AND SUMMARY

This Alternative Source Demonstration (ASD) report has been prepared to address a statistically significant increase (SSI) for fluoride in the groundwater monitoring network at the H.W. Pirkey Power Plant's Landfill, located in Hallsville, Texas, following the first semiannual detection monitoring event of 2020. The Landfill is registered as an ash landfill under Texas Commission on Environmental Quality (TCEQ) Industrial and Hazardous Waste Solid Waste Registration No. 33240. The western side of the Landfill overlies a former lignite mining area, as shown in **Figure 1**.

Background groundwater concentrations for the Landfill were initially calculated in January 2018 with data from at least eight monitoring events (Geosyntec, 2018). Upper prediction limits (UPLs) were calculated for each Appendix III parameter to represent background values. Lower prediction limits (LPLs) were also calculated for pH. An alternative source demonstration (ASD) was certified on January 7, 2020 which resulted in a revision from interwell tests to intrawell tests for pH, sulfate, and TDS prediction limits due to the presence of lignite mine spoils within the screened interval at downgradient well AD-34 (Geosyntec, 2020). Prediction limits were calculated based on a one-of-two retesting procedure to maintain an appropriate site-wide false positive rate (SWFPR). With this procedure, an SSI is concluded only if both samples in a series of two exceed the UPL or, in the case of pH, are below the LPL. In practice, if the initial result did not exceed the UPL, a second sample was not collected or analyzed.

The first semi-annual detection monitoring event of 2020 was performed in June 2020 (initial sampling event), and the results were compared to the calculated prediction limits. Where initial exceedances were identified, verification resampling was completed in July 2020. Following verification resampling, an SSI for fluoride was identified at well AD-34 by intrawell analysis, A summary of the detection monitoring analytical results and the calculated prediction limits to which they were compared is provided in **Table 1**.

1.1 CCR Rule Requirements

USEPA regulations regarding assessment monitoring programs for CCR landfills and surface impoundments provide owners and operators with the option to make an alternative source demonstration when an SSI is identified (40 CFR 257.94(e)(2)). An owner or operator may:

> *Demonstrate that a source other than the CCR unit caused the statistically significant increase over background levels for a constituent or that the statistically significant increase resulted from error in sampling, analysis, statistical evaluation, or natural variation in groundwater quality. The owner or operator must complete the written demonstration within 90 days of detecting a statistically significant increase over background levels to include obtaining a*

> *certification from a qualified professional engineer… verifying the accuracy of the information in the report.*

Pursuant to 40 CFR 257.94(e)(2), Geosyntec Consultants, Inc. (Geosyntec) has prepared this Alternative Source Demonstration (ASD) report to document that the SSI identified for fluoride at AD-34 is from a source other than the Landfill.

1.2 Demonstration of Alternative Sources

An evaluation was completed to assess possible alternative sources to which the identified SSI could be attributed. Alternative sources were identified amongst five types, based on methodology provided by EPRI (2017):

- ASD Type I: Sampling Causes;
- ASD Type II: Laboratory Causes;
- ASD Type III: Statistical Evaluation Causes;
- ASD Type IV: Natural Variation; and
- ASD Type V: Alternative Sources.

A demonstration was conducted to show that the SSI identified for fluoride at AD-34 was based on a Type IV cause and not by a release from the Pirkey Landfill.

SECTION 2

ALTERNATIVE SOURCE DEMONSTRATION

The Federal CCR Rule allows the owner or operator 90 days from the determination of an SSI to demonstrate that a source other than the CCR unit caused the SSI. The methodology used to evaluate the fluoride SSI and the proposed alternative source are described below.

2.1 Proposed Alternative Source – Natural Variation

An initial review of site geochemistry, site historical data, and laboratory quality assurance/quality control (QA/QC) data did not identify ASDs due to Type I (sampling), Type II (laboratory), or Type III (statistical evaluation) issues. Groundwater sampling, laboratory analysis, and statistical evaluations were generally completed in accordance with draft TCEQ guidance for groundwater monitoring (TCEQ, 2020). As described below, the SSI has been attributed to natural variation, which is a Type IV issue.

In February 2019, a Landfill leachate sample was collected for laboratory analysis to support an ASD for cobalt and cadmium (Burns & McDonnell, 2019). The results of this sample found that fluoride was detected at an estimated (J-flagged) concentration of 0.50 milligrams per liter (mg/L). The laboratory analytical report is provided as **Attachment A**. This concentration is below the intrawell UPL of 1.00 mg/L at AD-34, suggesting that the Landfill is not the likely source of the fluoride exceedance.

Fluoride concentrations at the site appear to be highly variable, including at background monitoring locations. Observed concentrations at background well AD-8 are consistently higher than those observed at AD-34 (**Figure 2**). The second semi-annual detection sampling event was conducted on November 4, 2020. The reported fluoride concentration for the sample from well AD-34 was 0.82 mg/L, which is below the calculated UPL (**Figure 3**). Based on recent results at AD-34, including the three samples collected during the 2020 groundwater monitoring events, a statistically significant positive trend is not demonstrated (**Figure 4**). Thus, the observed fluoride concentrations during the first semi-annual event are not considered indicative of a release from the LF and are instead likely due to natural variability in the aquifer.

A cause of the variability of dissolved fluoride concentrations may be associated with former mining activities that took place immediately underlying and downgradient of the Landfill. As has been noted in previous ASDs (Burns & McDonnell, 2019; Geosyntec, 2019; Geosyntec, 2020), AD-34 is screened within lignite mine spoils, which has significantly impacted its groundwater composition. An analysis of lignite in a well core advanced in the Wilcox formation, which is the material formerly mined in Area A, found that fluorine was present in the material at concentrations ranging from approximately 10 to 50 milligrams per kilogram of dry material (mg/kg dry lignite) (Chakrabouti et. al, 1984). It is feasible that fluorine could be mobilized from the mine spoils, resulting in variability in the aqueous fluoride concentrations at AD-34.

An additional line of evidence that the Landfill is likely not affecting groundwater at AD-34 is the lack of increasing concentrations for chloride. Chloride is a conservative constituent which is not significantly attenuated by chemical processes during advective flow. The concentration ratio between chloride and fluoride in groundwater varies between approximately 10:1 and 100:1 at both upgradient and downgradient locations (**Figure 5**). Chloride was detected in the Landfill leachate at 640 mg/L (**Attachment A**), which is approximately two orders of magnitude greater than the concentrations detected at AD-34. The concentration ratio between chloride and fluoride in the Landfill leachate is approximately 1200:1 (**Figure 5**), which suggests that dissolved chloride concentrations at AD-34 would be higher if this location were affected by leachate. As shown in **Figure 6**, the concentration of chloride is consistently around 7 mg/L, which is comparable to upgradient monitoring locations. A trend analysis found no significant increasing trend for chloride at AD-34 (**Figure 7**). Because chloride is a conservative constituent and concentrations are higher in the leachate, if the Landfill were affecting the groundwater composition, we would expect to observe an increasing trend of dissolved chloride at AD-34.

The lack of elevated fluoride in the Landfill leachate, the high concentration of fluoride at upgradient location AD-8, and the presence of fluorine in lignite mined within the footprint of the Landfill all indicate that the Landfill is not the likely source of elevated fluoride at AD-34.

2.2 Sampling Requirements

As the ASD described above supports the position that the identified fluoride SSI is not due to a release from the Pirkey Landfill, the unit will remain in the detection monitoring program. Groundwater at the unit will continue to be sampled for Appendix III parameters on a semi-annual basis.

SECTION 3

CONCLUSIONS AND RECOMMENDATIONS

The preceding information serves as the ASD prepared in accordance with 40 CFR 257.94(e)(2) and supports the position that the fluoride SSI at AD-34 identified during the first semiannual detection monitoring event of 2020 was not due to a release from the Landfill. The identified SSI was, instead, attributed to natural variation in the aquifer associated with former mining activities. Therefore, no further action is warranted, and the Pirkey Landfill will remain in the detection monitoring program. Certification of this ASD by a qualified professional engineer is provided in **Attachment B**.

4.10 – Statistical Analysis Summary, East Bottom Ash Pond, H.W. Pirkey Power Plant, Hallsville, Texas, January 3, 2018

Purpose of Statistical Analysis Summary Report

During the initial phase of ground water monitoring, the CCR rule requires AEP to collect at least eight independent samples from at least one up-gradient and three downgradient wells for 21 substances listed in the CCR rule. The CCR rule also requires us to select a statistical method that will be used to evaluate the samples in the later phases of the ground water monitoring program. The Statistical Plan, which has been posted to AEP's CCR website, describes the methods selected by AEP. *See* AEP's Statistical Analysis Plans.

Each **Statistical Analysis Summary Report** is based on the results of the 8 independent samples that were collected by October 17, 2017, and reported in the Annual Groundwater Monitoring Report. Using the statistical methods chosen by AEP, the samples were evaluated to eliminate outliers, determine variability and general trends in the data, and establish background values for: boron, calcium chloride, fluoride, pH, sulfate, and total dissolved solids. Appendix IV substances were evaluated for purposes of identifying outliers and understanding data trends.

A subsequent sample taken during the first detection monitoring sampling event was also compared using the proper statistical methods to the background values that were established for these seven substances from the eight independent samples. A second or third re-sampling event occurred, and the results compared using the same methods. This work is reported in the memorandum included in attachment A. If confirmed, AEP will be required to enter the next phase of monitoring. The results of future sampling will be further analyzed to target any specific substances for which ongoing monitoring or potential corrective action is required.

SECTION 1

EXECUTIVE SUMMARY

In accordance with the United States Environmental Protection Agency's (USEPA's) regulations regarding the disposal of coal combustion residuals (CCR) in landfills and surface impoundments (40 CFR 257.90-257.98, "CCR rule"), groundwater monitoring has been conducted at the East Bottom Ash Pond (EBAP), an existing CCR unit at the H.W. Pirkey Power Plant located in Hallsville, Texas.

Eight monitoring events were completed prior to October 17, 2017 to establish background concentrations for Appendix III and Appendix IV parameters under the CCR rule. Groundwater data underwent several validation tests, including those for completeness, sample tracking accuracy, transcription errors, and consistent use of measurement units. No data quality issues were identified which would impact the usability of the data.

The monitoring data were submitted to Groundwater Stats Consulting, LLC for statistical analysis. The background data were reviewed for outliers, which were removed (when appropriate) prior to calculating upper prediction limits (UPLs) for each Appendix III parameter to represent background values. Oversight on the use of statistical calculations was provided by Dr. Kirk Cameron of MacStat Consulting, Ltd.

A groundwater sampling event occurred on August 23 and 24, 2017 at the EBAP. This sampling event obtained the first sample for the 1-of-2 prediction interval statistical test used for detection monitoring. The results of this sampling event are included in this report.

SECTION 2

EAST BOTTOM ASH POND EVALUATION

2.1 Data Validation & QA/QC

During the background monitoring program, eight sets of samples were collected for analysis from each upgradient and compliance well. A summary of data collected during background and detection monitoring sampling may be found in Table 1.

Chemical analysis was completed by an analytical laboratory certified by the National Environmental Laboratory Accreditation Program (NELAP). Quality assurance and quality control (QA/QC) samples completed by the analytical laboratory included the use of laboratory reagent blanks (LRBs), continuing calibration verification (CCV) samples, and laboratory fortified blanks (LFBs).

The analytical data were imported into a Microsoft Access database, where checks were completed to assess the accuracy of sample location identification and analyte identification. Where necessary, unit conversions were applied to standardize reported units across all sampling events. Exported data files were created for use with the Sanitas™ v.9.5.32 statistics software. The export was checked against the analytical data for transcription errors and completeness. No QA/QC issues were noted which would impact data usability.

2.2 Statistical Analysis

The background data used to conduct the statistical analyses and the detection monitoring data are summarized in Table 1. Statistical analyses for the EBAP were conducted in accordance with the January 2017 *Statistical Analysis Plan* (AEP, 2017), except where noted below. Results for all completed statistical tests are provided in Attachment A.

Time series plots of Appendix III and IV parameters are included in Attachment A. Mann-Kendall analyses ($\alpha = 0.01$) were conducted to evaluate trends in the background data. Beryllium was found to be significantly decreasing at upgradient well AD-18. Boron was found to be significantly increasing at compliance well AD-2. No other significant increasing or decreasing trends were observed for other parameters or at other monitoring wells.

2.2.1 Background Outlier Evaluation

Potential outliers were identified using Tukey's outlier test; i.e., data points were considered potential outliers if they met one of the following criteria:

$$x_i < \tilde{x}_{0.25} - 3 \times IQR \quad (1)$$

or

$$x_i > \tilde{x}_{0.75} + 3 \times IQR \quad (2)$$

where:

$x_i =$ individual data point
$\tilde{x}_{0.25} =$ first quartile
$\tilde{x}_{0.75} =$ third quartile
$IQR =$ the interquartile range $= \tilde{x}_{0.75} - \tilde{x}_{0.25}$

Data that were evaluated as potential outliers are summarized in Attachment A. Tukey's outlier test identified 14 potential outliers, which are summarized in Table 2. Next, the data were reviewed to identify possible sources of errors or discrepancies, including data recording errors, unusual sampling conditions, laboratory quality indicators, or inconsistent sample turbidity. The findings of this data review are summarized below.

While the reported fluoride concentration of 4.717 mg/L at upgradient well AD-12 on October 12, 2016 was not identified as an outlier by Tukey's method, the duplicate sample was more similar to other upgradient data and therefore considered more representative of background. This value was replaced with the reported fluoride concentration for the duplicate sample also collected at AD-12. The statistical analysis was rerun using the duplicate result's reporting limit of 1.0 mg/L, as fluoride was not detected in the duplicate. The duplicate sample was considered more representative based on the reported concentrations from the other background sampling events.

Seven parameters (arsenic, barium, calcium, chromium, cobalt, lead, and mercury) were identified as potential outliers during the May 11, 2016 sampling event at compliance well AD-31. These results suggest an issue with sample collection and the values were removed from the dataset. The reported lead value of 0.00154 mg/L at AD-31 during the October 12, 2016 sampling event was also identified as a potential outlier. Lead was generally not detected at a reporting limit of 0.005 mg/L at AD-31. As the potential outlier was an estimated value and likely reflects concentrations within the aquifer, this value was retained within the database.

The reported chloride concentration of 20 mg/L at compliance well AD-2 on September 7, 2016 and the reported lithium concentration of 0.016 mg/L at compliance well AD-32 on May 11, 2016 were both identified as potential outliers. Both of these values were kept in the dataset as they reflected concentrations in nearby compliance wells.

The remaining three potential outliers did not have an apparent reason for their elevated value and was removed as recommended by USEPA's *Unified Guidance* (USEPA, 2009). The three outliers that were removed were associated with compliance monitoring wells; therefore, their removal did not affect the calculation of background levels presented below. Additionally, two of the outliers were associated with Appendix IV parameters, for which background levels were not calculated.

2.2.2 Establishment of Background Levels

Analysis of variance (ANOVA) was conducted to determine whether spatial variation was present among the three upgradient wells (Attachment A). ANOVA indicated no significant variation among the three upgradient wells for fluoride. Consequently, interwell tests were used for fluoride. Significant variation was observed for boron, calcium, chloride, pH, sulfate, and total dissolved solids (TDS). Therefore, the appropriateness of using intrawell tests was evaluated for these parameters at the Pirkey EBAP.

Intrawell tests presume that the groundwater quality in the compliance wells was not initially impacted by the CCR unit. To test this presumption, the data from the upgradient wells were pooled and the data from each compliance well were compared to a pooled background value. Tolerance limits were calculated using the pooled background data for boron, calcium, chloride, pH, sulfate, and TDS. Parametric tolerance limits with 99% confidence and 95% coverage were calculated for boron, chloride, pH, and TDS; non-parametric tolerance limits were calculated for calcium and sulfate, given the greater spatial variability observed for these two parameters. Confidence intervals were calculated for each of these six parameters at each compliance monitoring well. If the lower confidence limit from a compliance well exceeded the upper tolerance limit for the pooled background data, it was concluded that groundwater concentrations at compliance wells were above background concentrations. In these instances, intrawell tests would not be appropriate. However, these analyses indicated no significant exceedances for pH; elevated concentrations of boron, calcium, chloride, sulfate, and TDS were observed. (Non-parametric analyses also indicated no significant exceedances for pH and elevated concentrations of boron, chloride, and TDS in compliance wells.) Therefore, intrawell tests were used to evaluate potential SSIs for pH. Interwell tests were used to evaluate potential SSIs for boron, calcium, chloride, fluoride, sulfate, and TDS.

After equality of variance was tested and identified outliers were removed (where appropriate), a parametric or non-parametric analysis was selected based on the distribution of the data and the frequency of non-detect data. Estimated results less than the practical quantitation limit (PQL) – i.e., “J-flagged” data – were considered detections and the estimated results were used in the statistical analyses. Non-parametric analyses were selected for datasets with at least 50% non-detect data or datasets that could not be normalized. Parametric analyses were selected for datasets that passed the Shapiro-Wilk / Shapiro-Francía test for normality. The Kaplan-Meier non-detect adjustment was applied to datasets with between 15% and 50% non-detect data. For datasets with fewer than 15% non-detect data, non-detect data were replaced with one half of the PQL. The selected analysis (i.e., parametric or non-parametric) for each background dataset is shown in Attachment A.

Upper prediction limits (UPLs) were calculated for each Appendix III parameter to represent background values. A lower prediction limit (LPL) was also calculated for pH. To conduct the intrawell tests for pH, a separate UPL was calculated for each compliance well. To conduct the interwell tests for boron, calcium, chloride, fluoride, sulfate, and TDS, a single prediction interval was calculated for each of these parameters using pooled data from the three upgradient wells. The background data used for the UPL calculations are summarized in Table 1; the calculated UPLs are summarized in Table 3.

A significant increasing trend in boron concentrations was observed at compliance well AD-2. However, the rate of change in boron concentrations is low relative to absolute boron concentrations at AD-2. For this reason, the increasing trend in boron concentrations at AD-2 is not currently considered indicative of a release from the EBAP CCR unit.

UPLs were calculated for a one-of-two retesting procedure; i.e., if at least one sample in a series of two does not exceed the UPL, then it can be concluded that an SSI has not occurred. In practice, where initial results did not exceed the UPL, a second sample was not collected. The one-of-two retesting procedure allowed achieving an acceptably high statistical power while maintaining a site-wide false-positive rate (SWFPR) of 10% per year or less. Power curves were constructed for the interwell and intrawell parametric tests and are compared with the EPA Reference Power Curve in Attachment A. The power curves associated with the statistical tests for the Pirkey Plant EBAP exceed the EPA Reference Power Curve at 3 and 4 standard deviations; this is considered a "good" level of statistical power according to EPA's *Unified Guidance* (USEPA, 2009).

2.2.3 Certification by Qualified Professional Engineer

I certify that the selected and above described statistical method is appropriate for evaluating the groundwater monitoring data for the H.W. Pirkey East Bottom Ash Pond CCR management area and that the requirements of 40 CFR 257.93(f) have been met.

2.3 Conclusions

Eight background monitoring events and one detection monitoring event were completed in accordance with the CCR Rule. The laboratory and field data were reviewed prior to statistical analysis, with no QA/QC issues identified that impacted data usability. A review of outliers identified fourteen potential outliers, with ten values removed from the dataset without replacement. Prediction intervals were constructed based on the remaining background data and a one-of-two retesting procedure. Interwell tests were selected for boron, calcium, chloride, fluoride, sulfate, and TDS, whereas intrawell tests were selected for pH.

Memorandum

Date:	February 27, 2018
To:	David Miller (AEP)
Copies to:	Terence Wehling (AEP)
From:	Allison Kreinberg and Bruce Sass, Ph.D. (Geosyntec)
Subject:	Evaluation of Detection Monitoring Data at Pirkey Plant's East Bottom Ash Pond (EBAP)

In accordance with the United States Environmental Protection Agency's (USEPA's) regulations regarding the disposal of coal combustion residuals (CCR) in landfills and surface impoundments (40 CFR 257.90-257.98, "CCR rule"), detection monitoring events were completed on August 23-24 and December 21, 2017 at the East Bottom Ash Pond (EBAP), an existing CCR unit at the Pirkey Power Plant located in Hallsville, Texas.

Eight background monitoring events were conducted at the Pirkey EBAP prior to these detection monitoring events, and upper prediction limits (UPLs) were calculated for each Appendix III parameter to represent background values. A lower prediction limit (LPL) was also calculated for pH. Details on the calculation of these background values are described in Geosyntec's *Statistical Analysis Summary* report, dated January 3, 2018.

To achieve an acceptably high statistical power while maintaining a site-wide false-positive rate (SWFPR) of 10% per year or less, prediction limits were calculated based on a one-of-two retesting procedure. With this procedure, a statistically significant increase (SSI) is only concluded if both samples in a series of two exceeds the UPL. In practice, if the initial result did not exceed the UPL, a second sample was not collected or analyzed.

Detection monitoring results and the relevant background values are summarized in Table 1b.

- Boron concentrations exceeded the interwell UPL of 0.0482 mg/L in both the initial (1.46 mg/L) and second (1.38 mg/L) samples collected at AD-2, and in both the initial (0.716 mg/L) and second (2.56 mg/L) samples collected at AD-32. Therefore, an SSI over background is concluded for boron at AD-2 and AD-32.

- Calcium concentrations exceeded the interwell UPL of 2.94 mg/L in both the initial (7.15 mg/L) and the second (17.1 mg/L) samples collected at AD-32. Therefore, an SSI over background is concluded for calcium at AD-32.

- Chloride concentrations exceeded the interwell UPL of 8.51 mg/L in both the initial (24 mg/L) and second (24 mg/L) samples collected at AD-2, in both the initial (18 mg/L) and second (20 mg/L) samples collected at AD-31, and in both the initial (14 mg/L) and second (22 mg/L) samples collected at AD-32. Therefore, an SSIs over background is concluded for chloride at AD-2, AD-31, and AD-32.

- Total dissolved solids (TDS) concentrations exceeded the interwell UPL of 174 mg/L in both the initial (200 mg/L) and second (206 mg/L) samples collected at AD-2, in both the initial (228 mg/L) and second (224 mg/L) samples collected at AD-31, and in both the initial (288 mg/L) and second (504 mg/L) samples collected at AD-32. Therefore, an SSI over the background is concluded for TDS at AD-2, AD-31, and AD-32.

- Sulfate concentrations exceeded the interwell UPL of 23 mg/L in both the initial (64 mg/L) and second (64 mg/L) samples collected at AD-2, in both the initial (52 mg/L) and second (58 mg/L) samples collected at AD-31, and in both the initial (115 mg/L) and second (324 mg/L) samples collected at AD-32. Therefore, an SSI over the background is concluded for sulfate at AD-2, AD-31, and AD-32.

As a result, the Pirkey EBAP CCR unit will conduct an alternate source demonstration. No other exceedances of UPLs were observed during these detection monitoring events.

The following modifications to Geosyntec's *Statistical Analysis Summary* report were incorporated after the certification date of January 3, 2018:

- Table 1 ("Groundwater Data Summary") was revised to reflect appropriate significant digits for estimated (J-flagged) values; and,

- Figure E ("Analysis of Variance") of Attachment A ("Statistical Analysis Output") was revised to correct a formatting error.

* * * * *

CERTIFICATION BY QUALIFIED PROFESSIONAL ENGINEER

I certify that the selected statistical method, described above and in the January 3, 2018 *Statistical Analysis Summary* report, is appropriate for evaluating the groundwater monitoring data for the Pirkey EBAP CCR management area and that the requirements of 40 CFR 257.93(f) have been met.

GROUNDWATER STATS
CONSULTING

November 5, 2017

Geosyntec Consultants
Attn: Mr. Bruce Sass
150 E. Wilson Bridge Rd., #232
Worthington, OH 43085

Dear Mr. Sass,

Groundwater Stats Consulting, formerly the statistical consulting division of Sanitas Technologies, is pleased to provide the screening and statistical analysis of background groundwater data for American Electric Power's East Bottom Ash Pond. The analysis complies with the federal rule for the Disposal of Coal Combustion Residuals from Electric Utilities (CCR Rule, 2015) as well as with the USEPA Unified Guidance (2009).

Sampling began at East Bottom Ash Pond for the CCR program in 2016, and 8 background samples have been collected at each of the groundwater monitoring wells. The monitoring well network, as provided by Geosyntec Consultants, consists of the following: upgradient wells AD-4, AD-12, and AD-18; and downgradient wells AD-2, AD-31, and AD-32A.

Data were sent electronically to Groundwater Stats Consulting, and the statistical analysis was reviewed by Dr. Kirk Cameron, PhD Statistician with MacStat Consulting, primary author of the USEPA Unified Guidance, and Senior Advisor to Groundwater Stats Consulting.

The following constituents were evaluated: Appendix III parameters – boron, calcium, chloride, fluoride, pH, sulfate, and TDS; and Appendix IV parameters - antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, combined radium 226 & 228, fluoride, lead, lithium, mercury, molybdenum, selenium, and thallium.

Time series plots for Appendix III and IV parameters at all wells are provided for the purpose of screening data at these wells (Figure A). Additionally, box plots are included for all constituents at upgradient and downgradient wells (Figure B). The time series plots are used to initially screen for suspected outliers and trends, while the box plots provide visual representation of variation within individual wells and between all wells.

Data at all wells were evaluated for the following: 1) outliers; 2) trends; 3) most appropriate statistical method for Appendix III parameters based on site characteristics of groundwater data upgradient of the facility; and 4) eligibility of downgradient wells when intrawell statistical methods are recommended. Power curves are provided to demonstrate that the selected statistical methods for Appendix III parameters comply with the USEPA Unified Guidance recommendations as discussed below.

Summary of Statistical Method:

1) Intrawell prediction limits, combined with a 1-of-2 resample plan for pH;
2) Interwell prediction limits combined with a 1-of-2 resample plan for boron, calcium, chloride, fluoride, sulfate and TDS.

Parametric prediction limits are utilized when the screened historical data follow a normal or transformed-normal distribution. When data cannot be normalized or the majority of data are nondetects, a nonparametric test is utilized. The distribution of data is tested using the Shapiro-Wilk/Shapiro-Francia test for normality. After testing for normality and performing any adjustments as discussed below (US EPA, 2009), data are analyzed using either parametric or non-parametric prediction limits.

- No statistical analyses are required on wells and analytes containing 100% nondetects (USEPA Unified Guidance, 2009, Chapter 6).
- When data contain <15% nondetects in background, simple substitution of one-half the reporting limit is utilized in the statistical analysis. The reporting limit utilized for nondetects is the practical quantification limit (PQL) as reported by the laboratory.
- When data contain between 15-50% nondetects, the Kaplan-Meier nondetect adjustment is applied to the background data. This technique adjusts the mean and standard deviation of the historical concentrations to account for concentrations below the reporting limit.
- Nonparametric prediction limits are used on data containing greater than 50% nondetects.

Background Screening

Outlier Evaluation

Time series plots are used to identify suspected outliers, or extreme values that would result in limits that are not conservative from a regulatory perspective, in proposed background data. Suspected outliers at all wells for Appendix III and Appendix IV parameters were formally tested using Tukey’s box plot method and, when identified, flagged in the computer database with “o” and deselected prior to construction of statistical limits (Figure C).

Tukey’s outlier test noted several outliers as may be seen on the Outlier Summary Table and accompanying graphs. Any values flagged as outliers are plotted in a lighter font on the time series graph. While the test identified a couple low outliers for chloride, lead and lithium in downgradient wells, these values were not flagged because they were similar in concentration to surrounding wells. It was noted that the first background sample in well AD-31 for several constituents was higher than all subsequent samples. This could be representative of well drilling processes, or an indication of sampling or analytical error. Therefore, these values were flagged as outliers since they do not appear to represent the population of groundwater at this well. In some cases, the test could not identify suspect outliers due to the upper and lower quartiles being equal. When extreme values were present in background, however, they were flagged as outliers, such as fluoride in upgradient well AD-12. A substitution of the most recent reporting limit was applied when varying detection limits existed in data.

No true seasonal patterns were observed on the time series plots for any of the detected data; therefore, no deseasonalizing adjustments were made to the data. When seasonal patterns are observed, data may be deseasonalized so that the resulting limits will correctly account for the seasonality as a predictable pattern rather than random variation or a release.

While trends may be visual, a quantification of the trend and its significance is needed. The Sen's Slope/Mann Kendall trend test was used to evaluate all data at each well to identify statistically significant increasing or decreasing trends (Figure D). In the absence of suspected contamination, significant trending data are typically not included as part of the background data used for construction of prediction limits. This step serves to eliminate the trend and, thus, reduce variation in background. When statistically significant decreasing trends are present, earlier data are evaluated to determine whether earlier concentration levels are significantly different than current reported concentrations and will be deselected as necessary. When the historical records of data are truncated for the reasons above, a summary report will be provided to show the date ranges used in construction of the statistical limits.

The results of the trend analyses showed a couple statistically significant increasing and decreasing trends, as may be seen on the Trend Test Summary Table that accompanies the trend tests. These trends are relatively low in magnitude when compared to average concentrations; therefore, no adjustments were made to the data sets.

Appendix III – Determination of Spatial Variation

The Analysis of Variance (ANOVA) was used to statistically evaluate differences in average concentrations among upgradient wells, which assists in identifying the most appropriate statistical approach (Figure E). Interwell tests, which compare downgradient well data to statistical limits constructed from pooled upgradient well data, are appropriate when average concentrations are similar across upgradient wells. Intrawell tests, which compare compliance data from a single well to screened historical data within the same well, are appropriate when upgradient wells exhibit spatial variation; when statistical limits constructed from upgradient wells would not be conservative from a regulatory perspective; and when downgradient water quality is unimpacted compared to upgradient water quality for the same parameter.

The ANOVA identified no variation for fluoride, making this constituent suitable for interwell analyses. Variation was identified in groundwater upgradient of the site for all other Appendix III parameters. Therefore, these data were further evaluated as described for the appropriateness of intrawell testing to accommodate the groundwater quality. A summary table of the ANOVA results is included with the reports.

Appendix III - Statistical Limits

Intrawell limits constructed from carefully screened background data from within each well serve to provide statistical limits that are conservative (i.e. lower) from a regulatory perspective, and that will rapidly identify a change in more recent compliance data from within a given well. This statistical method removes the element of variation from across wells and eliminates the chance of mistaking natural spatial variation for a release from the facility. Prior to performing intrawell prediction limits, several steps are required to reasonably demonstrate downgradient water quality does not have existing impacts from the practices of the facility.

Exploratory data analysis was used as a general comparison of concentrations in downgradient wells for all Appendix III parameters recommended for intrawell analyses to concentrations reported in upgradient wells. Upper tolerance limits are used in conjunction with confidence intervals to determine whether the estimated averages in downgradient wells are higher than observed levels upgradient of the facility. The upper tolerance limits were constructed to represent the extreme upper range of possible background levels at the site.

In cases where downgradient average concentrations are higher than observed concentrations upgradient for a given constituent, an independent study and hydrogeological investigation would be required to identify local geochemical conditions and expected groundwater quality for the region to justify an intrawell approach. Such an assessment is beyond the scope of services provided by Groundwater Stats Consulting. When there is not an obvious explanation for observed concentration differences in downgradient wells relative to reported concentrations in upgradient wells, interwell prediction limits will initially be selected for the statistical method until further evidence shows that concentrations are due to natural variation rather than a result of the facility.

Parametric tolerance limits were constructed with a target of 99% confidence and 95% coverage using pooled upgradient well data for each of the Appendix III parameters recommended for intrawell analyses (Figure F). The confidence and coverage levels for nonparametric tolerance limits are dependent upon the number of background samples. As more data are collected, the background population is better represented and the confidence and coverage levels increase.

Confidence intervals were constructed on downgradient wells for each of the Appendix III parameters, using the tolerance limits discussed above, to determine intrawell eligibility for parameters exhibiting spatial variation (Figure G). When the entire confidence interval is above a background standard for a given parameter, interwell methods are initially recommended as the statistical method. Therefore, only parameters with confidence intervals which did not exceed background standards are eligible for intrawell prediction limits.

Confidence intervals for the above parameters were found to be within their respective background limit for pH, while the confidence intervals for all other Appendix III parameters evaluated were above the background standards for parameters exhibiting spatial variation. Therefore, intrawell methods are recommended for pH at this time, and interwell methods are recommended initially for all other Appendix III parameters. As mentioned earlier, if a demonstration supports natural variation in groundwater, intrawell methods will be considered for all parameters.

All available data through April 2017 at each well were used to establish intrawell background limits based on a 1-of-2 resample plan that will be used for future comparisons (Figure H). Interwell prediction limits, combined with a 1-of-2 resample plan, were constructed from upgradient wells for the Appendix III parameters discussed above (Figure I). Downgradient measurements will be compared to these background limits during each subsequent semi-annual sampling event.

Natural systems continuously evolve due to physical changes made to the environment. Examples include capping a landfill, paving areas near a well, or lining a drainage channel to prevent erosion. Periodic updating of background statistical limits will be necessary to accommodate these types of changes In the interwell case, newer data will be included in background when a minimum of 2 new samples from each upgradient well are available. In the intrawell case, data for all wells and constituents are re-evaluated when a minimum of 4 new data points from each well are available to determine whether earlier concentrations are representative of present-day groundwater quality. In some cases, the earlier portion of data are deselected prior to construction of limits in order to provide sensitive limits that will rapidly detect changes in groundwater quality. Even though the data are excluded from the calculation, the values will continue to be reported and shown in tables and graphs.

In the event of an initial exceedance of compliance well data, the 1-of-2 resample plan allows for collection of an additional sample to determine whether the initial exceedance is confirmed. When the resample confirms the initial exceedance, a statistically significant increase (SSI) is identified and further research would be required to identify the cause of the exceedance (i.e. impact from the site, natural variation, or an off-site source). If the resample falls within the statistical limit, the initial exceedance is considered to be a false positive result and, therefore, no further action is necessary. A summary table of the background prediction limits follows this letter.

Appendix IV – Assessment Monitoring Program

During an Assessment Monitoring program confidence intervals are constructed at all wells for detected Appendix IV parameters. A minimum of 4 samples is required to construct confidence intervals; however, 8 samples are generally recommended for better representation of the true average population. Established Maximum Contaminant Levels (MCLs) are used as the GWPS comparisons, unless background limits are higher as discussed below. Parametric confidence intervals are constructed with 99% confidence when data follow a normal or transformed-normal distribution. For all other cases, nonparametric confidence intervals are constructed, with the confidence level based on the number of samples available. The GWPS is exceeded only when the entire confidence interval exceeds its respective GWPS.

Background limits are established for the Appendix IV parameters using upper tolerance limits constructed with 95% confidence/95% coverage using pooled upgradient well data, for comparison against established MCLs. When background limits, or Alternate Contaminant Levels (ACLs), are higher than established MCLs, the CCR Rule recommends using these ACLs as the GWPS for the confidence interval comparisons. Additionally, tolerance limits are also recommended to establish ACLs for Appendix IV parameters, cobalt, lithium, and molybdenum, which do not have established MCLs. Since the scope of this project included screening and development of background limits for Appendix III Detection Monitoring statistics, comparison of the Appendix IV parameters with confidence intervals was not included in this report.

Recommendations

In summary, as a result of the background screening described in this letter, intrawell prediction limits combined with a 1-of-2 resample plan are recommended for pH. Interwell prediction limits combined with a 1-of-2 resample plan are recommended for boron, calcium, chloride, fluoride, sulfate, and TDS. The statistical analyses will be constructed according to the USEPA Unified Guidance, based on seven Appendix III parameters and three downgradient wells.

Thank you for the opportunity to assist you in the statistical analysis of groundwater quality for the East Bottom Ash Pond. If you have any questions or comments, please feel free to contact me.

Tukey's Outlier Screening

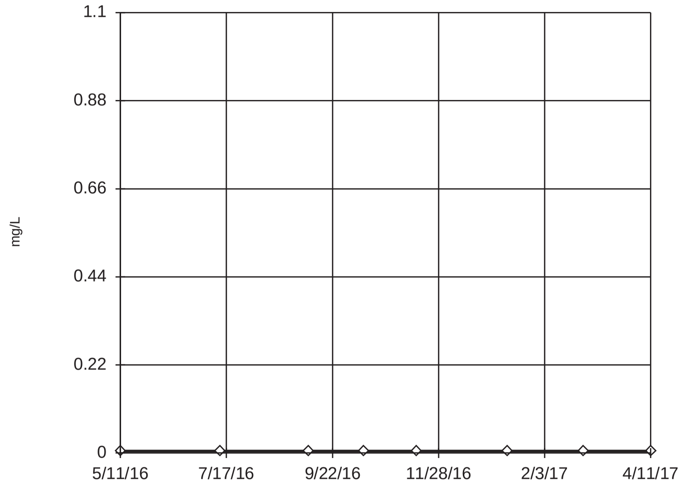
AD-31



n = 8

No outliers found.
Tukey's method used in lieu of parametric test because the Shapiro Wilk normality test failed at the 0.05 alpha level.

Data were natural log transformed to achieve best W statistic (graph shown in original units).

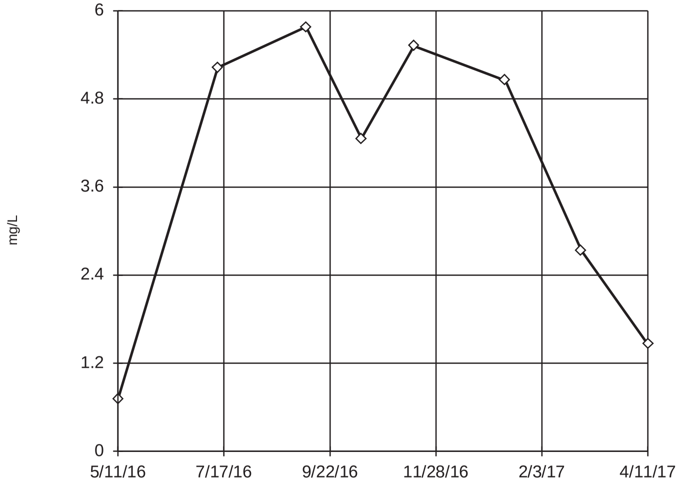
High cutoff = 0.09481, low cutoff = 0.01266, based on IQR multiplier of 3.

Constituent: Boron, total Analysis Run 11/5/2017 8:53 AM View: Tukey's Screen Downgradient
Pirkey EBAP Client: Geosyntec Data: Pirkey EBAP

Sanitas™ v.9.6.00 Groundwater Stats Consulting. UG

Tukey's Outlier Screening

AD-32



n = 8

No outliers found.
Tukey's method selected by user.

Data were x^4 transformed to achieve best W statistic (graph shown in original units).

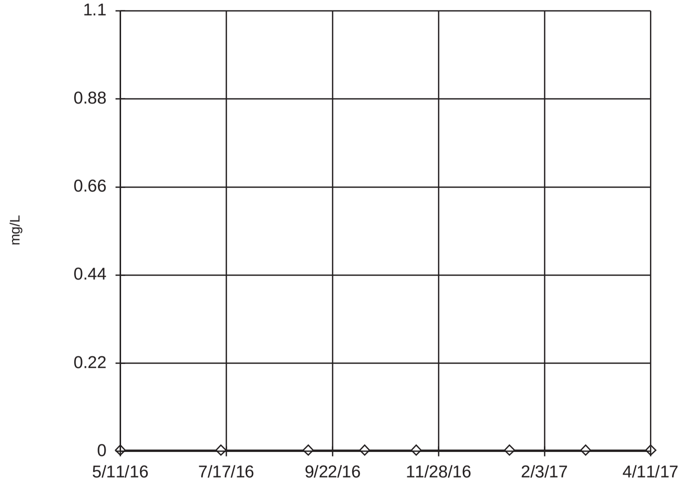
High cutoff = 7.558, low cutoff = -6.995, based on IQR multiplier of 3.

Constituent: Boron, total Analysis Run 11/5/2017 8:53 AM View: Tukey's Screen Downgradient
Pirkey EBAP Client: Geosyntec Data: Pirkey EBAP

Sanitas™ v.9.6.00 Groundwater Stats Consulting. UG

Tukey's Outlier Screening

AD-2



n = 8

No outliers found.
Tukey's method used in lieu of parametric test because the Shapiro Wilk normality test failed at the 0.05 alpha level.

Data were cube root transformed to achieve best W statistic (graph shown in original units).

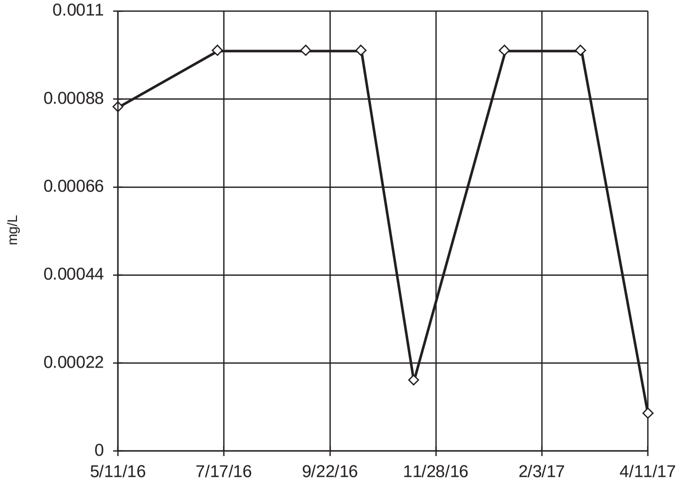
The results were invalidated, because the lower and upper quartiles are equal.

Constituent: Cadmium, total Analysis Run 11/5/2017 8:53 AM View: Tukey's Screen Downgradient
Pirkey EBAP Client: Geosyntec Data: Pirkey EBAP

Sanitas™ v.9.6.00 Groundwater Stats Consulting. UG

Tukey's Outlier Screening

AD-31



n = 8

No outliers found.
Tukey's method used in lieu of parametric test because the Shapiro Wilk normality test failed at the 0.05 alpha level.

Data were x^6 transformed to achieve best W statistic (graph shown in original units).

The results were invalidated, because both the lower and upper quartiles represent reporting limits.

Constituent: Cadmium, total   Analysis Run 11/5/2017 8:53 AM   View: Tukey's Screen Downgradient
